1. **Purpose**

*nag_opt_lsq_deriv (e04gbc)* is a comprehensive algorithm for finding an unconstrained minimum of a sum of squares of \( m \) nonlinear functions in \( n \) variables (\( m \geq n \)). First derivatives are required. The function *nag_opt_lsq_deriv* is intended for objective functions which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. **Specification**

```c
#include <nag.h>
#include <nage04.h>

void nag_opt_lsq_deriv(Integer m, Integer n,
                        void (*lsqfun)(Integer m, Integer n, double x[], double fvec[],
                                       double fjac[], Integer tdj, Nag_Comm *comm),
                        double x[], double *fsumsq, double fvec[], double fjac[],
                        Integer tdj, Nag_E04_Opt *options, Nag_Comm *comm, NagError *fail)
```

3. **Description**

This function is applicable to problems of the form:

\[
\text{Minimize } F(x) = \sum_{i=1}^{m} [f_i(x)]^2
\]

where \( x = (x_1, x_2, \ldots, x_n)^T \) and \( m \geq n \). (The functions \( f_i(x) \) are often referred to as ‘residuals’.) The user must supply a C function to calculate the values of the \( f_i(x) \) and their first derivatives \( \frac{\partial f_i}{\partial x_j} \) at any point \( x \).

From a starting point \( x^{(1)} \), supplied by the user, *nag_opt_lsq_deriv* generates a sequence of points \( x^{(2)}, x^{(3)}, \ldots \), which is intended to converge to a local minimum of \( F(x) \). The sequence of points is given by

\[
x^{(k+1)} = x^{(k)} + \alpha^{(k)} p^{(k)}
\]

where the vector \( p^{(k)} \) is a direction of search, and \( \alpha^{(k)} \) is chosen such that \( F(x^{(k)} + \alpha^{(k)} p^{(k)}) \) is approximately a minimum with respect to \( \alpha^{(k)} \).

The vector \( p^{(k)} \) used depends upon the reduction in the sum of squares obtained during the last iteration. If the sum of squares was sufficiently reduced, then \( p^{(k)} \) is the Gauss-Newton direction; otherwise the second derivatives of the \( f_i(x) \) are taken into account using a quasi-Newton updating scheme.

The method is designed to ensure that steady progress is made whatever the starting point, and to have the rapid ultimate convergence of Newton’s method.

4. **Parameters**

- **m**
  - Input: the number \( m \) of residuals, \( f_i(x) \)

- **n**
  - Input: the number \( n \) of variables, \( x_j \).
  - Constraint: \( 1 \leq n \leq m \).

- **lsqfun**
  - The function \( lsqfun \), supplied by the user, must calculate the vector of values \( f_i(x) \) and their first derivatives \( \frac{\partial f_i}{\partial x_j} \) at any point \( x \). (However, if the user does not wish to calculate the residuals at a particular \( x \), there is the option of setting a parameter to cause *nag_opt_lsq_deriv* to terminate immediately.)
The specification of \texttt{lsqfun} is:

```c
void lsqfun(Integer m, Integer n, double x[], double fvec[],
            double fjac[], Integer tdj, Nag_Comm *comm)
```

- \texttt{m}
  - Input: the numbers \(m\) and \(n\) of residuals and variables, respectively.

- \texttt{n}
  - Input: the point \(x\) at which the values of the \(f_i\) and the \(\partial f_i/\partial x_j\) are required.

- \texttt{fvec[m]}
  - Output: unless \texttt{comm->flag} = 1 on entry, or \texttt{comm->flag} is reset to a negative number, then \texttt{fvec[i - 1]} must contain the value of \(f_i\) at the point \(x\), for \(i = 1, 2, \ldots, m\).

- \texttt{fjac[m*tdj]}
  - Output: unless \texttt{comm->flag} = 0 on entry, or \texttt{comm->flag} is reset to a negative number, then \texttt{fjac[(i-1)*tdj + j - 1]} must contain the value of the first derivative \(\partial f_i/\partial x_j\) at the point \(x\), for \(i = 1, 2, \ldots, m; j = 1, 2, \ldots, n\).

- \texttt{tdj}
  - Input: the second dimension of the array \texttt{fjac} as declared in the function from which \texttt{nag_opt_lsq_deriv} is called.

- \texttt{comm}
  - Pointer to structure of type \texttt{Nag_Comm}; the following members are relevant to \texttt{lsqfun}.
    - \texttt{flag} – Integer
      - Input: \texttt{comm->flag} contains 0, 1 or 2. The value 0 indicates that only the residuals need to be evaluated, the value 1 indicates that only the Jacobian matrix needs to be evaluated, and the value 2 indicates that both the residuals and the Jacobian matrix must be calculated. (If the default value of the optional parameter \texttt{options.minlin} is used, \texttt{Nag_Lin_Deriv}, then \texttt{lsqfun} will always be called with \texttt{comm->flag} set to 2.)
      - Output: if \texttt{lsqfun} resets \texttt{comm->flag} to some negative number then \texttt{nag_opt_lsq_deriv} will terminate immediately with the error indicator \texttt{NE_USER_STOP}. If \texttt{fail} is supplied to \texttt{nag_opt_lsq_deriv}, \texttt{fail.errnum} will be set to the user’s setting of \texttt{comm->flag}.
    - \texttt{first} – Boolean
      - Input: will be set to \texttt{TRUE} on the first call to \texttt{lsqfun} and \texttt{FALSE} for all subsequent calls.
    - \texttt{nf} – Integer
      - Input: the number of calls made to \texttt{lsqfun} including the current one.
    - \texttt{user} – double *
    - \texttt{iuser} – Integer *
    - \texttt{p} – Pointer
      - The type \texttt{Pointer} will be \texttt{void *} with a C compiler that defines \texttt{void *} and \texttt{char *} otherwise.
      - Before calling \texttt{nag_opt_lsq_deriv} these pointers may be allocated memory by the user and initialised with various quantities for use by \texttt{lsqfun} when called from \texttt{nag_opt_lsq_deriv}.

Note: \texttt{lsqfun} should be tested separately before being used in conjunction with \texttt{nag_opt_lsq_deriv}. Function \texttt{nag_opt_lsq_check_deriv (e04yac)} may be used to check the derivatives. The array \texttt{x} must not be changed within \texttt{lsqfun}.

- \texttt{x[n]}
  - Input: \texttt{x[j - 1]} must be set to a guess at the \(j\)th component of the position of the minimum, for \(j = 1, 2, \ldots, n\).
Output: the final point $x^*$. On successful exit, $x[j-1]$ is the $j$th component of the estimated position of the minimum.

**fsumsq**
Output: the value of $F(x)$, the sum of squares of the residuals $f_i(x)$, at the final point given in $x$.

**fvec[m]**
Output: $fvec[i-1]$ is the value of the residual $f_i(x)$ at the final point given in $x$, for $i = 1, 2, \ldots, m$.

**fjac[m][tdj]**
Output: $fjac[i-1][j-1]$ contains the value of the first derivative $\partial f_i/\partial x_j$ at the final point given in $x$, for $i = 1, 2, \ldots, m$; $j = 1, 2, \ldots, n$.

**tdj**
Input: the second dimension of the array $fjac$ as declared in the function from which $nag_opt_lsq_deriv$ is called.
Constraint: $tdj \geq n$.

**options**
Input/Output: a pointer to a structure of type Nag_E04_Opt whose members are optional parameters for $nag_opt_lsq_deriv$. These structure members offer the means of adjusting some of the parameter values of the algorithm and on output will supply further details of the results. A description of the members of **options** is given below in Section 7.
If any of these optional parameters are required then the structure **options** should be declared and initialised by a call to $nag_opt_init$ (e04xxc) and supplied as an argument to $nag_opt_lsq_deriv$. However, if the optional parameters are not required the NAG defined null pointer, **E04_DEFAULT**, can be used in the function call.

**comm**
Input/Output: structure containing pointers for communication to user-supplied functions; see the above description of **lsqfun** for details. If the user does not need to make use of this communication feature the null pointer **NAGCOMM_NULL** may be used in the call to $nag_opt_lsq_deriv$; **comm** will then be declared internally for use in calls to user-supplied functions.

**fail**
The NAG error parameter, see the Essential Introduction to the NAG C Library.
Users are recommended to declare and initialise **fail** and set **fail.print** = **TRUE** for this function.

### 4.1. Description of Printed Output

Intermediate and final results are printed out by default. The level of printed output can be controlled by the user with the option **print_level** (see Section 7.2.). The default print level of **Nag_Soln_Iter** provides a single line of output at each iteration and the final result.
The line of results printed at each iteration gives:

- **Itn**: the current iteration number $k$.
- **Nfun**: the cumulative number of calls to **lsqfun**.
- **Objective**: the current value of the objective function, $F(x^{(k)})$.
- **Norm g**: the Euclidean norm of the gradient of $F(x^{(k)})$.
- **Norm x**: the Euclidean norm of $x^{(k)}$.
- **Norm(x(k-1)-x(k))**: the Euclidean norm of $x^{(k-1)} - x^{(k)}$.
- **Step**: the step $\alpha^{(k)}$ taken along the computed search direction $p^{(k)}$.

The printout of the final result consists of:

- **x**: the final point $x^*$.
- **g**: the gradient of $F$ at the final point.
- **Residuals**: the values of the residuals $f_i$ at the final point.
- **Sum of squares**: the value of $F(x^*)$, the sum of squares of the residuals at the final point.
5. Comments

A list of possible error exits and warnings from nag_opt_lsq_deriv is given in Section 8.

5.1. Preliminary comments on accuracy

If the problem is reasonably well scaled and a successful exit is made, then, for a computer with a mantissa of $t$ decimals, one would expect to get about $t/2 - 1$ decimals accuracy in the components of $x$ and between $t - 1$ (if $F(x)$ is of order 1 at the minimum) and $2t - 2$ (if $F(x)$ is close to zero at the minimum) decimals accuracy in $F(x)$.

Further details about accuracy are given in Section 9.

6. Example 1

To find least-squares estimates of $x_1, x_2$ and $x_3$ in the model

$$y = x_1 + \frac{t_1}{x_2 t_2 + x_3 t_3}$$

using the 15 sets of data given in the following table.

<table>
<thead>
<tr>
<th></th>
<th>$t_1$</th>
<th>$t_2$</th>
<th>$t_3$</th>
</tr>
</thead>
<tbody>

</table>

The program uses (0.5, 1.0, 1.5) as the initial guess at the position of the minimum.

This example shows the simple use of nag_opt_lsq_deriv where default values are used for all optional parameters. An example showing the use of optional parameters is given in Section 12. There is however only one example program file, the main program of which calls both examples. The main program and example 1 are given below.

7. Optional Parameters

A number of optional input and output parameters to nag_opt_lsq_deriv are available through the structure argument options, type Nag_E04_Opt. A parameter may be selected by assigning an appropriate value to the relevant structure member; those parameters not selected will be assigned default values. If no use is to be made of any of the optional parameters the user should use the NAG defined null pointer, E04_DEFAULT, in place of options when calling nag_opt_lsq_deriv; the default settings will then be used for all parameters.

Before assigning values to options directly the structure must be initialised by a call to the function nag_opt_init (e04xxc). Values may then be assigned to the structure members in the normal C manner.
Option settings may also be read from a text file using the function nag_opt_read (e04xyc) in which case initialisation of the options structure will be performed automatically if not already done. Any subsequent direct assignment to the options structure must not be preceded by initialisation.

If assignment of functions and memory to pointers in the options structure is required, this must be done directly in the calling program. They cannot be assigned using nag_opt_read (e04xyc).

7.1. Optional Parameter Checklist and Default Values

For easy reference, the following list shows the members of options which are valid for nag_opt_lsq_deriv together with their default values where relevant. The number \( \epsilon \) is a generic notation for machine precision (see nag_machine_precision (X02AJC)).

<table>

7.2. Description of Optional Parameters

- **list** – Boolean
  Default = TRUE
  Input: if options.list = TRUE the parameter settings in the call to nag_opt_lsq_deriv will be printed.

- **print_level** – Nag_PrintType
  Default = Nag_Soln_Iter
  Input: the level of results printout produced by nag_opt_lsq_deriv. The following values are available:
  - Nag_NoPrint: No output.
  - Nag_Soln: The final solution.
  - Nag_Iter: One line of output for each iteration.
  - Nag_Soln_Iter: The final solution and one line of output for each iteration.
  - Nag_Soln_Iter_Full: The final solution and detailed printout at each iteration.
  Details of each level of results printout are described in Section 7.3.
  Constraint: options.print_level = Nag_NoPrint or Nag_Soln or Nag_Iter or Nag_Soln_Iter or Nag_Soln_Iter_Full.

- **outfile** – char [80]
  Default = stdout
  Input: the name of the file to which results should be printed. If options.outfile[0] = '\0' then the stdout stream is used.

- **print_fun** – pointer to function
  Default = NULL
  Input: printing function defined by the user; the prototype of print_fun is
  \[
  \text{void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm);} \]
  See Section 7.3.1 below for further details.

- **deriv_check** – Boolean
  Default = TRUE
  Input: if options.deriv_check = TRUE a check of the derivatives defined by lsqfun will be made at the starting point x. The derivative check is carried out by a call to nag_opt_lsq_check_deriv (e04yac). A starting point of \( x = 0 \) or \( x = 1 \) should be avoided if this test is to be meaningful, but if either of these starting points is necessary then nag_opt_lsq_check_deriv (e04yac) should be used to check lsqfun at a different point prior to calling nag_opt_lsq_deriv.
\textbf{max_iter} – Integer  
Input: the limit on the number of iterations allowed before termination. 
Constraint: \texttt{options.max_iter} \geq 0.

\textbf{optim_tol} – double  
Input: the accuracy in $x$ to which the solution is required. 
If $x_{true}$ is the true value of $x$ at the minimum, then $x_{sol}$, the estimated position prior to a normal exit, is such that 
\[
||x_{sol} - x_{true}|| < \text{optim\_tol} \times (1.0 + ||x_{true}||),
\]
where $||y|| = \sum_{j=1}^{n} y_j^2$. For example, if the elements of $x_{sol}$ are not much larger than 1.0 in modulus and if $\text{optim\_tol} = 1.0 \times 10^{-5}$, then $x_{sol}$ is usually accurate to about 5 decimal places. (For further details see Section 9.) 
If $F(x)$ and the variables are scaled roughly as described in Section 9 and $\epsilon$ is the \textit{machine precision}, then a setting of order $\text{optim\_tol} = \sqrt{\epsilon}$ will usually be appropriate. 
Constraint: $10\epsilon \leq \text{options.optim\_tol} < 1.0$.

\textbf{minlin} – \texttt{Nag\_LinFun}  
Default = \texttt{Nag\_Lin\_Deriv} 
Input: \texttt{minlin} specifies whether the linear minimizations (i.e., minimizations of $F(x(k) + \alpha(k)p(k))$ with respect to $\alpha(k)$) are to be performed by a function which just requires the evaluation of the $f_j(x)$, \texttt{Nag\_Lin\_NoDeriv}, or by a function which also requires the first derivatives of the $f_j(x)$, \texttt{Nag\_Lin\_Deriv}. 
It will often be possible to evaluate the first derivatives of the residuals in about the same amount of computer time that is required for the evaluation of the residuals themselves – if this is so then \texttt{nag\_opt\_lsq\_deriv} should be called with \texttt{minlin} set to \texttt{Nag\_Lin\_Deriv}. However, if the evaluation of the derivatives takes more than about 4 times as long as the evaluation of the residuals, then a setting of \texttt{Nag\_Lin\_NoDeriv} will usually be preferable. If in doubt, use the default setting \texttt{Nag\_Lin\_Deriv} as it is slightly more robust. 
Constraint: \texttt{options.minlin} = \texttt{Nag\_Lin\_Deriv} or \texttt{Nag\_Lin\_NoDeriv}.

\textbf{linesearch} – double  
Default = 0.9. (If \texttt{n} = 1, default = 0.0) 
If \texttt{options.minlin} is set to \texttt{Nag\_Lin\_NoDeriv} then the default value of \texttt{linesearch\_tol} will be changed from 0.9 to 0.5 if \texttt{n} > 1. 
Input: \texttt{linesearch\_tol} specifies how accurately the linear minimizations are to be performed. 
Every iteration of \texttt{nag\_opt\_lsq\_deriv} involves a linear minimization i.e., minimization of $F(x(k) + \alpha(k)p(k))$ with respect to $\alpha(k)$. The minimum with respect to $\alpha(k)$ will be located more accurately for small values of \texttt{linesearch\_tol} (say 0.01) than for large values (say 0.9). Although accurate linear minimizations will generally reduce the number of iterations performed by \texttt{nag\_opt\_lsq\_deriv}, they will increase the number of calls of \texttt{lsqfun} made each iteration. On balance it is usually more efficient to perform a low accuracy minimization. 
Constraint: $0.0 \leq \text{options.linesearch\_tol} < 1.0$.

\textbf{step\_max} – double  
Default = 100000.0 
Input: an estimate of the Euclidean distance between the solution and the starting point supplied by the user. (For maximum efficiency, a slight overestimate is preferable.) \texttt{nag\_opt\_lsq\_deriv} will ensure that, for each iteration, 
\[
\sum_{j=1}^{n} (x_j^{(k)} - x_j^{(k-1)})^2 \leq (\text{step\_max})^2
\]
where $k$ is the iteration number. Thus, if the problem has more than one solution, \texttt{nag\_opt\_lsq\_deriv} is most likely to find the one nearest to the starting point. On difficult problems, a realistic choice can prevent the sequence $x^{(k)}$ entering a region where the problem is ill-behaved and can help avoid overflow in the evaluation of $F(x)$. However, an underestimate of \texttt{options.step\_max} can lead to inefficiency. 
Constraint: \texttt{options.step\_max} \geq \text{options.optim\_tol}.
### nag_opt_lsq_deriv

**s** – double *

Default memory = n

Input: n values of memory will be automatically allocated by nag_opt_lsq_deriv and this is the recommended method of use of options.s. However a user may supply memory from the calling program.

Output: the singular values of the Jacobian matrix at the final point. Thus options.s may be useful as information about the structure of the user’s problem.

**v** – double *

Default memory = n*n

Input: n*n values of memory will be automatically allocated by nag_opt_lsq_deriv and this is the recommended method of use of options.v. However a user may supply memory from the calling program.

Output: the matrix V associated with the singular value decomposition $J = USV^T$ of the Jacobian matrix at the final point, stored by rows. This matrix may be useful for statistical purposes, since it is the matrix of orthonormalised eigenvectors of $J^TJ$.

**tdv** – Integer

Default = n

Input: if memory is supplied by the user then options.tdv must contain the last dimension of the array assigned to options.tdv as declared in the function from which nag_opt_lsq_deriv is called.

Output: the trailing dimension used by options.v. If the NAG default memory allocation has been used this value will be n.

Constraint: options.tdv ≥ n.

**grade** – Integer

Output: the grade of the Jacobian at the final point. nag_opt_lsq_deriv estimates the dimension of the subspace for which the Jacobian matrix can be used as a valid approximation to the curvature (see Gill and Murray, 1978); this estimate is called the grade.

**iter** – Integer

Output: the number of iterations which have been performed in nag_opt_lsq_deriv.

**nf** – Integer

Output: the number of times the residuals have been evaluated (i.e., the number of calls of lsqfun).

### 7.3. Description of Printed Output

The level of printed output can be controlled with the structure members options.list and options.print_level (see Section 7.2.). If list = TRUE then the parameter values to nag_opt_lsq_deriv are listed, whereas the printout of results is governed by the value of print_level. The default of print_level = Nag_Soln_Iter provides a single line of output at each iteration and the final result. This section describes all of the possible levels of results printout available from nag_opt_lsq_deriv.

When options.print_level = Nag_Iter or Nag_Soln_Iter a single line of output is produced on completion of each iteration, this gives the following values:

- **It**n
- Nfun
- Objective
- Norm g
- Norm x
- Norm(x(k-1)−x(k))
- Step

When options.print_level = Nag_Soln_Iter_Full more detailed results are given at each iteration. Additional values output are

- **Grade**
- x
- g

the grade of the Jacobian matrix. (See description of grade, Section 7.2)

the current point $x^{(k)}$.

the current gradient of $F(x^{(k)})$.
Singular values the singular values of the current approximation to the Jacobian matrix.

If `options.print_level = Nag_Soln` or `Nag_Soln_Iter` or `Nag_Soln_Iter_Full` the final result consists of:

- **x**: the final point $x^*$.
- **g**: the gradient of $F$ at the final point.
- **Residuals**: the values of the residuals $f_i$ at the final point.
- **Sum of squares**: the value of $F(x^*)$, the sum of squares of the residuals at the final point.

If `options.print_level = Nag_NoPrint` then printout will be suppressed; the user can print the final solution when `nag_opt_lsq_deriv` returns to the calling program.

### 7.3.1. Output of results via a user defined printing function

Users may also specify their own print function for output of iteration results and the final solution by use of the `options.print_fun` function pointer, which has prototype:

```c
void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm);
```

The rest of this section can be skipped if the default printing facilities provide the required functionality.

When a user defined function is assigned to `options.print_fun` this will be called in preference to the internal print function of `nag_opt_lsq_deriv`. Calls to the user defined function are again controlled by means of the `options.print_level` member. Information is provided through `st` and `comm`, the two structure arguments to `print_fun`. If `comm->it_prt = TRUE` then the results from the last iteration of `nag_opt_lsq_deriv` are in the following members of `st`:

- **m**: Integer
  - the number of residuals.
- **n**: Integer
  - the number of variables.
- **x**: double *
  - points to the `n` memory locations holding the current point $x^{(k)}$.
- **fvec**: double *
  - points to the `m` memory locations holding the values of the residuals $f_i$ at the current point $x^{(k)}$.
- **fjac**: double *
  - points to `m*st->tdj` memory locations. $fjac[(i-1)*st->tdj + (j-1)]$ contains the value of $\frac{\partial f_i}{\partial x_j}$, for $i = 1, 2, \ldots, m$; $j = 1, 2, \ldots, n$ at the current point $x^{(k)}$.
- **tdj**: Integer
  - the trailing dimension for `st->fjac[]`.
- **step**: double
  - the step $\alpha^{(k)}$ taken along the search direction $p^{(k)}$.
- **xk_norm**: double
  - the Euclidean norm of $x^{(k-1)} - x^{(k)}$.
- **g**: double *
  - points to the `n` memory locations holding the gradient of $F$ at the current point $x^{(k)}$.
- **grade**: Integer
  - the grade of the Jacobian matrix.
- **s**: double *
  - points to the `n` memory locations holding the singular values of the current Jacobian.
- **iter**: Integer
  - the number of iterations, $k$, performed by `nag_opt_lsq_deriv`.
- **nf**: Integer
  - the cumulative number of calls made to `lsqfun`. 

[NP3275/5/pdf] 3.e04gbc.11
The relevant members of the structure **comm** are:

- **it_pr**t – Boolean
  will be **TRUE** when the print function is called with the result of the current iteration.

- **sol_pr**t – Boolean
  will be **TRUE** when the print function is called with the final result.

- **user** – double *
- **iuser** – Integer *
- **p** – Pointer
  pointers for communication of user information. If used they must be allocated memory by
  the user either before entry to **nag_opt_lsq_deriv** or during a call to **lsqfun** or **print_fun**. The
  type Pointer will be **void** * with a C compiler that defines **void** * and **char** * otherwise.

8. **Error Indications and Warnings**

**NE_USER_STOP**
User requested termination, user flag value = ⟨value⟩.

This exit occurs if the user sets **comm**→**flag** to a negative value in **lsqfun**. If **fail** is supplied
the value of **fail.errnum** will be the same as the user's setting of **comm**→**flag**.

**NE_INT_ARG_LT**
On entry, **n** must not be less than 1: **n** = ⟨value⟩.

**NE_2_INT_ARG_LT**
On entry, **m** = ⟨value⟩ while **n** = ⟨value⟩. These parameters must satisfy **m** ≥ **n**.
On entry, **tdj** = ⟨value⟩ while **n** = ⟨value⟩. These parameters must satisfy **tdj** ≥ **n**.

**NE_DERIV_ERRORS**
Large errors were found in the derivatives of the objective function.

The user should check carefully the derivation and programming of expressions for
the ∂fᵢ/∂xⱼ, because it is very unlikely that **lsqfun** is calculating them correctly.

**NE_OPT_NOT_INIT**
Options structure not initialised.

**NE_BAD_PARAM**
On entry parameter **options.print_level** had an illegal value.
On entry parameter **options.minlin** had an illegal value.

**NE_2_INT_ARG_LT**
On entry, **options.tdv** = ⟨value⟩ while **n** = ⟨value⟩. These parameters must satisfy **tdv** ≥ **n**.

**NE_2_REAL_ARG_LT**
On entry, **options.step_max** = ⟨value⟩ while **options.optim_tol** = ⟨value⟩. These parameters
must satisfy **step_max** ≥ **optim_tol**.

**NE_INVALID_INT_RANGE_1**
Value ⟨value⟩ given to **options.max_iter** not valid. Correct range is **max_iter** ≥ 0.

**NE_INVALID_REAL_RANGE_EF**
Value ⟨value⟩ given to **options.optim_tol** not valid. Correct range is ⟨value⟩ ≤ **optim_tol** < 1.0.

**NE_INVALID_REAL_RANGE_FF**
Value ⟨value⟩ given to **options.linesearch_tol** not valid. Correct range is 0.0 ≤ **linesearch_tol** ≤ 1.0.

**NE_ALLOC_FAIL**
Memory allocation failed.

If one of the above exits occurs, no values will have been assigned to **fsumsq**, or to the elements of
**fvec**, **fjac**, **options.s** or **options.v**.
NW_TOO_MANY_ITER
The maximum number of iterations, $\langle\text{value}\rangle$, have been performed.

If steady reductions in the sum of squares, $F(x)$, were monitored up to the point where this exit occurred, then the exit probably occurred simply because max_iter was set too small, so the calculations should be restarted from the final point held in $x$. This exit may also indicate that $F(x)$ has no minimum.

NW_COND_MIN
The conditions for a minimum have not all been satisfied, but a lower point could not be found.

This could be because options.optim_tol has been set so small that rounding errors in the evaluation of the residuals make attainment of the convergence conditions impossible.

NE_SVD_FAIL
The computation of the singular value decomposition of the Jacobian matrix has failed to converge in a reasonable number of sub-iterations.

It may be worth applying nag_opt lsq deriv again starting with an initial approximation which is not too close to the point at which the failure occurred.

The exits NW_TOO_MANY_ITER, NW_COND_MIN, and NE_SVD_FAIL may also be caused by mistakes in lsqfun, by the formulation of the problem or by an awkward function. If there are no such mistakes it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure.

NE_NOT_APPEND_FILE
Cannot open file $\langle\text{string}\rangle$ for appending.

NE_WRITE_ERROR
Error occurred when writing to file $\langle\text{string}\rangle$.

NE_NOT_CLOSE_FILE
Cannot close file $\langle\text{string}\rangle$.

9. Further Comments
The number of iterations required depends on the number of variables, the number of residuals, the behaviour of $F(x)$, the accuracy demanded and the distance of the starting point from the solution. The number of multiplications performed per iteration of nag_opt lsq deriv varies, but for $m \gg n$ is approximately $n \times m^2 + O(n^3)$. In addition, each iteration makes at least one call of lsqfun. So, unless the residuals can be evaluated very quickly, the run time will be dominated by the time spent in lsqfun.

Ideally, the problem should be scaled so that, at the solution, $F(x)$ and the corresponding values of the $x_j$ are each in the range $(-1, 1)$, and so that at points one unit away from the solution, $F(x)$ differs from its value at the solution by approximately one unit. This will usually imply that the Hessian matrix of $F(x)$ at the solution is well-conditioned. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that nag_opt lsq deriv will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to nag_opt lsq covariance (e04ycc), using information returned in the arrays options.s and options.v. See nag_opt lsq covariance (e04ycc) for further details.

9.1. Accuracy
A successful exit (fail.code = NE_NOERROR) is made from nag_opt lsq_deriv when (B1, B2 and B3) or B4 or B5 hold, where

\begin{align*}
B1 & \equiv \alpha(k) \times \| p^{(k)} \| < (\text{optim_tol} + \epsilon) \times (1.0 + \| x^{(k)} \|) \\
B2 & \equiv \| F^{(k)} - F^{(k-1)} \| < (\text{optim_tol} + \epsilon)^2 \times (1.0 + F^{(k)}) \\
B3 & \equiv \| g^{(k)} \| < \epsilon^{1/3} \times (1.0 + F^{(k)}) \\
B4 & \equiv F^{(k)} < \epsilon^2 \\
B5 & \equiv \| g^{(k)} \| < (\epsilon \times \sqrt{F^{(k)}})^{1/2}
\end{align*}
and where $||.||$, $\epsilon$ and the optional parameter $\text{optim}\_\text{tol}$ are as defined in Section 7.2, while $F^{(k)}$ and $g^{(k)}$ are the values of $F(x)$ and its vector of first derivatives at $x^{(k)}$.

If fail.code = NE\_NOERROR then the vector in x on exit, $x_{sol}$, is almost certainly an estimate of $x_{true}$, the position of the minimum to the accuracy specified by $\text{options.optim}_\text{tol}$.

If fail.code = NW\_COND\_MIN, then $x_{sol}$ may still be a good estimate of $x_{true}$, but to verify this the user should make the following checks. If

(a) the sequence $\{F(x^{(k)})\}$ converges to $F(x_{sol})$ at a superlinear or a fast linear rate, and
(b) $g(x_{sol})^T g(x_{sol}) < 10\epsilon$,

where $T$ denotes transpose, then it is almost certain that $x_{sol}$ is a close approximation to the minimum. When (b) is true, then usually $F(x_{sol})$ is a close approximation to $F(x_{true})$.

Further suggestions about confirmation of a computed solution are given in the Chapter Introduction.

12. Example 2

Example 2 solves the same problem as Example 1 but shows the use of certain optional parameters. This example shows option values being assigned directly within the program text and by reading values from a data file. The $\text{options}$ structure is declared and initialised by nag\_opt\_init (e04xxc), a value is then assigned directly to option $\text{optim}_\text{tol}$ and two further options are read from the data file by use of nag\_opt\_read (e04xyc). The memory freeing function nag\_opt\_free (e04xzc) is used to free the memory assigned to the pointers in the option structure. Users should not use the standard C function free() for this purpose.
