NAG C Library Function Document

nag_dsteqr (f08jec)

1 Purpose

nag_dsteqr (f08jec) computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix, or of a real symmetric matrix which has been reduced to tridiagonal form.

2 Specification

```c
void nag_dsteqr (Nag_OrderType order, Nag_ComputeZType compz, Integer n,
                double d[], double e[], double z[], Integer pdz, NagError *fail)
```

3 Description

nag_dsteqr (f08jec) computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric tridiagonal matrix $T$. In other words, it can compute the spectral factorization of $T$ as

$$T = Z \Lambda Z^T,$$

where $\Lambda$ is a diagonal matrix whose diagonal elements are the eigenvalues $\lambda_i$, and $Z$ is the orthogonal matrix whose columns are the eigenvectors $z_i$. Thus

$$T z_i = \lambda_i z_i, \quad i = 1, 2, \ldots, n.$$

The function may also be used to compute all the eigenvalues and eigenvectors of a real symmetric matrix $A$ which has been reduced to tridiagonal form $T$:

$$A = QTQ^T, \quad \text{where } Q \text{ is orthogonal},$$

$$= (QZ) \Lambda (QZ)^T.$$  

In this case, the matrix $Q$ must be formed explicitly and passed to nag_dsteqr (f08jec), which must be called with `compz = Nag_UpdateZ`. The functions which must be called to perform the reduction to tridiagonal form and form $Q$ are:

- full matrix: nag_dsytrd (f08fec) + nag_dorgtr (f08ffc)
- full matrix, packed storage: nag_dsptrd (f08gec) + nag_dopgtr (f08gfc)
- band matrix: nag_dsbtrd (f08hec) with `vect = Nag_FormQ`.

nag_dsteqr (f08jec) uses the implicitly shifted QR algorithm, switching between the QR and QL variants in order to handle graded matrices effectively (see Greenbaum and Dongarra (1980)). The eigenvectors are normalized so that $\|z_i\|_2 = 1$, but are determined only to within a factor $\pm 1$.

If only the eigenvalues of $T$ are required, it is more efficient to call nag_dsterf (f08jfc) instead. If $T$ is positive-definite, small eigenvalues can be computed more accurately by nag_dpteqr (f08jgc).

4 References

5 Parameters

1: order – Nag_OrderType

On entry: the order parameter specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by order = Nag_RowMajor. See Section 2.2.1.4 of the Essential Introduction for a more detailed explanation of the use of this parameter.

Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: compz – Nag_ComputeZType

On entry: indicates whether the eigenvectors are to be computed as follows:

- if compz = Nag_NotZ, only the eigenvalues are computed (and the array z is not referenced);
- if compz = Nag_InitZ, the eigenvalues and eigenvectors of \( T \) are computed (and the array z is initialised by the routine);
- if compz = Nag_UpdateZ, the eigenvalues and eigenvectors of \( A \) are computed (and the array z must contain the matrix \( Q \) on entry).

Constraint: compz = Nag_NotZ, Nag_UpdateZ or Nag_InitZ.

3: n – Integer

On entry: \( n \), the order of the matrix \( T \).

Constraint: \( n \geq 0 \).

4: d[dim] – double

On entry: the diagonal elements of the tridiagonal matrix \( T \).

On exit: the \( n \) eigenvalues in ascending order, unless fail > 0 (in which case see Section 6).

Note: the dimension, \( dim \), of the array d must be at least \( \max(1, n) \).

5: e[dim] – double

On entry: the off-diagonal elements of the tridiagonal matrix \( T \).

On exit: the array is overwritten.

Note: the dimension, \( dim \), of the array e must be at least \( \max(1, n - 1) \).

6: z[dim] – double

On entry: if compz = Nag_UpdateZ, \( z \) must contain the orthogonal matrix \( Q \) from the reduction to tridiagonal form. If compz = Nag_InitZ, \( z \) must be allocated, but its contents need not be set. If compz = Nag_NotZ, \( z \) is not referenced and may be a NULL pointer, i.e., (double *) 0.

On exit: if compz = Nag_InitZ or Nag_UpdateZ, the \( n \) required orthonormal eigenvectors stored as columns of \( z \); the \( i \)th column corresponds to the \( i \)th eigenvalue, where \( i = 1, 2, \ldots, n \), unless fail > 0.

\( z \) is not changed if compz = Nag_NotZ.
7: pdz – Integer  

On entry: the first dimension of the array z as declared in the function from which nag_dsteqr (f08jec) is called. When z is a NULL pointer then pdz should be set to 0.

Constraints:

if \text{compz} = \text{Nag\_NotZ}, \text{pdz} \geq 0;
if \text{compz} = \text{Nag\_UpdateZ} \text{ or Nag\_InitZ}, \text{pdz} \geq \max(1, n).

8: fail – NagError *  

The NAG error parameter (see the Essential Introduction).

6 Error Indicators and Warnings

NE\_INT

On entry, n = \langle\text{value}\rangle.
Constraint: n \geq 0.

On entry, pdz = \langle\text{value}\rangle.
Constraint: pdz > 0.

NE\_ENUM\_INT\_2

On entry, compz = \langle\text{value}\rangle, n = \langle\text{value}\rangle, pdz = \langle\text{value}\rangle.
Constraint: if \text{compz} = \text{Nag\_UpdateZ} \text{ or Nag\_InitZ}, \text{pdz} \geq \max(1, n);  
if \text{compz} = \text{Nag\_NotZ}, \text{pdz} \geq 1.

On entry, compz = \langle\text{value}\rangle, n = \langle\text{value}\rangle, pdz = \langle\text{value}\rangle.
Constraint: if \text{compz} = \text{Nag\_UpdateZ} \text{ or Nag\_InitZ}, \text{pdz} \geq 0;  
if \text{compz} = \text{Nag\_NotZ}, \text{pdz} \geq \max(1, n).

On entry, n = \langle\text{value}\rangle, compz = \langle\text{value}\rangle, pdz = \langle\text{value}\rangle.
Constraint: if \text{compz} = \text{Nag\_UpdateZ} \text{ or Nag\_InitZ}, \text{pdz} \geq \max(1, n);  
if \text{compz} = \text{Nag\_NotZ}, \text{pdz} \geq 1.

NE\_CONVERGENCE

The algorithm has failed to find all the eigenvalues after a total of 30 \times n iterations; \langle\text{value}\rangle off-diagonal elements have not converged to zero. The parameters d and e contain the diagonal and off-diagonal elements, respectively, of a tridiagonal matrix orthogonally similar to T.

NE\_ALLOC\_FAIL

Memory allocation failed.

NE\_BAD\_PARAM

On entry, parameter \langle\text{value}\rangle had an illegal value.

NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

7 Accuracy

The computed eigenvalues and eigenvectors are exact for a nearby matrix T + E, where

\[ \|E\|_2 = O(\epsilon)\|T\|_2, \]

and \(\epsilon\) is the machine precision.
If \( \lambda_i \) is an exact eigenvalue and \( \tilde{\lambda}_i \) is the corresponding computed value, then

\[
|\tilde{\lambda}_i - \lambda_i| \leq c(n) \varepsilon \|T\|_2,
\]

where \( c(n) \) is a modestly increasing function of \( n \).

If \( z_i \) is the corresponding exact eigenvector, and \( \tilde{z}_i \) is the corresponding computed eigenvector, then the angle \( \theta(\tilde{z}_i, z_i) \) between them is bounded as follows:

\[
\theta(\tilde{z}_i, z_i) \leq \frac{c(n) \varepsilon \|T\|_2}{\min_{i \neq j} |\lambda_i - \lambda_j|}.
\]

Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues.

8 Further Comments

The total number of floating-point operations is typically about \( 24n^2 \) if \( \text{compz} = \text{Nag_NotZ} \) and about \( 7n^3 \) if \( \text{compz} = \text{Nag_UpdateZ} \) or \( \text{Nag_InitZ} \), but depends on how rapidly the algorithm converges. When \( \text{compz} = \text{Nag_NotZ} \), the operations are all performed in scalar mode; the additional operations to compute the eigenvectors when \( \text{compz} = \text{Nag_UpdateZ} \) or \( \text{Nag_InitZ} \) can be vectorized and on some machines may be performed much faster.

The complex analogue of this function is nag_zsteqr (f08jsc).

9 Example

To compute all the eigenvalues and eigenvectors of the symmetric tridiagonal matrix \( T \), where

\[
T = \begin{bmatrix}
-6.99 & -0.44 & 0.00 & 0.00 \\
-0.44 & 7.92 & -2.63 & 0.00 \\
0.00 & -2.63 & 2.34 & -1.18 \\
0.00 & 0.00 & -1.18 & 0.32 \\
\end{bmatrix},
\]

See also the examples for nag_dorgtr (f08ffc), nag_dopgtr (f08gfc) or nag_dsbtrd (f08hec), which illustrate the use of this function to compute the eigenvalues and eigenvectors of a full or band symmetric matrix.
