NAG C Library Function Document

nag_partial_corr (g02byc)

1 Purpose

nag_partial_corr (g02byc) computes a partial correlation/variance-covariance matrix from a correlation or variance-covariance matrix computed by nag_correl_cov (g02bxc).

2 Specification

```
#include <nag.h>
#include <nag02.h>

void nag_partial_corr(Integer m, Integer ny, Integer nx, const Integer siz[],
                     const double r[], Integer tdr, double p[], Integer tdp,
                     NagError *fail)
```

3 Description

Partial correlation can be used to explore the association between pairs of random variables in the presence of other variables. For three variables, $y_1$, $y_2$ and $x_3$ the partial correlation coefficient between $y_1$ and $y_2$ given $x_3$ is computed as:

$$
\frac{r_{12} - r_{13}r_{23}}{\sqrt{(1 - r_{13}^2)(1 - r_{23}^2)}},
$$

where $r_{ij}$ is the product-moment correlation coefficient between variables with subscripts $i$ and $j$. The partial correlation coefficient is a measure of the linear association between $y_1$ and $y_2$ having eliminated the effect due to both $y_1$ and $y_2$ being linearly associated with $x_3$. That is, it is a measure of association between $y_1$ and $y_2$ conditional upon fixed values of $x_3$. Like the full correlation coefficients the partial correlation coefficient takes a value in the range $(-1,1)$ with the value 0 indicating no association.

In general, let a set of variables be partitioned into two groups $Y$ and $X$ with $n_y$ variables in $Y$ and $n_x$ variables in $X$ and let the variance-covariance matrix of all $n_y + n_x$ variables be partitioned into:

$$
\begin{bmatrix}
\Sigma_{xx} & \Sigma_{xy} \\
\Sigma_{yx} & \Sigma_{yy}
\end{bmatrix}
$$

The variance-covariance of $Y$ conditional on fixed values of the $X$ variables is given by:

$$
\Sigma_{y|x} = \Sigma_{yy} - \Sigma_{yx}\Sigma_{xx}^{-1}\Sigma_{xy}
$$

The partial correlation matrix is then computed by standardising $\Sigma_{y|x}$,

$$
\text{diag}(\Sigma_{y|x})^{-\frac{1}{2}}\Sigma_{y|x}\text{diag}(\Sigma_{y|x})^{-\frac{1}{2}}.
$$

To test the hypothesis that a partial correlation is zero under the assumption that the data has an approximately Normal distribution a test similar to the test for the full correlation coefficient can be used. If $r$ is the computed partial correlation coefficient then the appropriate $t$ statistic is

$$
\frac{r}{\sqrt{\frac{n-n_x-2}{1-r^2}}},
$$

which has approximately a Student’s $t$-distribution with $n - n_x - 2$ degrees of freedom, where $n$ is the number of observations from which the full correlation coefficients were computed.
4 Parameters

1: \textbf{m} – Integer \hspace{1cm} \textit{Input}

\textit{On entry:} the number of variables in the variance-covariance/correlation matrix given in \textit{r}.

\textit{Constraint: m ≥ 3.}

2: \textbf{ny} – Integer \hspace{1cm} \textit{Input}

\textit{On entry:} the number of \textit{Y} variables, \textit{n_y}, for which partial correlation coefficients are to be computed.

\textit{Constraint: ny ≥ 2.}

3: \textbf{nx} – Integer \hspace{1cm} \textit{Input}

\textit{On entry:} the number of \textit{X} variables, \textit{n_x}, which are to be considered as fixed.

\textit{Constraints:}

\begin{align*}
\text{nx} & \geq 1, \\
\text{ny} + \text{nx} & \leq \text{m}.
\end{align*}

4: \textbf{sz[m]} – const Integer \hspace{1cm} \textit{Input}

\textit{On entry:} indicates which variables belong to set \textit{X} and \textit{Y}.

If \textit{sz}(i) < 0, then the \textit{i}th variable is a \textit{Y} variable, for \textit{i} = 1, 2, ..., \textit{m}.

If \textit{sz}(i) > 0, then the \textit{i}th variable is a \textit{X} variable.

If \textit{sz}(i) = 0, then the \textit{i}th variable is not included in the computations.

\textit{Constraints:}

exactly \textit{ny} elements of \textit{sz} must be < 0,

exactly \textit{nx} elements of \textit{sz} must be > 0.

5: \textbf{r[m][tdr]} – const double \hspace{1cm} \textit{Input}

\textit{On entry:} the variance-covariance or correlation matrix for the \textit{m} variables as given by \texttt{nag_coss_cov (g02bxc)}. Only the upper triangle need be given.

\textbf{Note:} the matrix must be a full rank variance-covariance or correlation matrix and so be positive-definite. This condition is not directly checked by the function.

6: \textbf{tdr} – Integer \hspace{1cm} \textit{Input}

\textit{On entry:} the second dimension of the array \textit{r} as declared in the function from which \texttt{nag_partial_coss} is called.

\textit{Constraint: tdr ≥ m.}

7: \textbf{p[ny][tdp]} – double \hspace{1cm} \textit{Output}

\textit{On exit:} the strict upper triangle of \textit{p} contains the strict upper triangular part of the \textit{n_y} by \textit{n_y} partial correlation matrix. The lower triangle contains the lower triangle of the \textit{n_y} by \textit{n_y} partial variance-covariance matrix if the matrix given in \textit{r} is a variance-covariance matrix. If the matrix given in \textit{r} is a correlation matrix then the variance-covariance matrix is for standardised variables.

8: \textbf{tdp} – Integer \hspace{1cm} \textit{Input}

\textit{On entry:} the second dimension of the array \textit{p} as declared in the function from which \texttt{nag_partial_coss} is called.

\textit{Constraint: tdp ≥ ny.}
9:  fail – NagError *

The NAG error parameter (see the Essential Introduction).

5  Error Indicators and Warnings

NE_INT_ARG_LT

On entry, m must not be less than 3: m = <value>.
On entry, ny must not be less than 2: ny = <value>.
On entry, nx must not be less than 1: nx = <value>.

NE_3_INT_ARG_CONS

On entry, ny = <value>, nx = <value> and m = <value>.
These parameters must satisfy ny + nx ≤ m.

NE_2_INT_ARG_LT

On entry, tdr = <value> while m = <value>.
These parameters must satisfy tdr ≥ m.
On entry, tdp = <value> while ny = <value>.
These parameters must satisfy tdp ≥ ny.

NE_BAD_NY_SET

On entry, ny = <value> and there are not exactly ny values of isz < 0.
Number of values of isz < 0 = <value>.

NE_BAD_NX_SET

On entry, nx = <value> and there are not exactly nx values of isz < 0.

NE_ALLOC_FAIL

Memory allocation failed.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

NE_COR_MAT_RANK

On entry, either the variance-covariance matrix or the correlation matrix is not of full rank. Try removing some of the x variables by setting the appropriate elements of isz to zero.

NE_COR_MAT_POSDEF

Either a diagonal element of the partial variance-covariance matrix is zero and/or a computed partial correlation coefficient is greater than one. Both indicate that the matrix input in r was not positive-definite.

6  Further Comments

Models that represent the linear associations given by partial correlations can be fitted using the multiple regression function nag_regn_multi_linear (g02dac).

6.1  Accuracy

nag_partial_cor computes the partial variance-covariance matrix, Σ_pj,r, by computing the Cholesky factorization of Σ_x,x. If Σ_x,x is not of full rank the computation will fail.

8 Example
Data, given by Osborn (1979), on the number of deaths, smoke (mg/m$^3$) and sulphur dioxide (parts/million) during an intense period of fog is input. The correlations are computed using nag_corr_cov (g02bxc) and the partial correlation between deaths and smoke given sulphur dioxide is computed using nag_partial_corr.
