1 Purpose

nag_surviv_risk_sets (g12zac) creates the risk sets associated with the Cox proportional hazards model for fixed covariates.

2 Specification

void nag_surviv_risk_sets (Nag_OrderType order, Integer n, Integer m, Integer ns, const double z[], Integer pdz, const Integer isize[], Integer ip, const double t[], const Integer ic[], const Integer isi[], Integer *num, Integer *ixs, Integer *nxs, double x[], Integer mxn, Integer id[], Integer *nd, double tp[], Integer irs[], NagError *fail)

3 Description

The Cox proportional hazards model (Cox (1972b)) relates the time to an event, usually death or failure, to a number of explanatory variables known as covariates. Some of the observations may be right censored, that is, the exact time to failure is not known, only that it is greater than a known time.

Let $t_i$ for $i = 1, 2, \ldots, n$ be the the failure time or censored time for the $i$th observation with the vector of $p$ covariates $z_i$. The covariance matrix $Z$ is constructed so that it contains $n$ rows with the $i$th row containing the $p$ covariates $z_i$. It is assumed that censoring and failure mechanisms are independent. The hazard function, $\lambda(t, z)$, is the probability that an individual with covariates $z$ fails at time $t$ given that the individual survived up to time $t$. In the Cox proportional hazards model, $\lambda(t, z)$ is of the form

$$ \lambda(t, z) = \lambda_0(t) \exp(z^T \beta), $$

where $\lambda_0$ is the base-line hazard function, an unspecified function of time, and $\beta$ is a vector of unknown parameters. As $\lambda_0$ is unknown, the parameters $\beta$ are estimated using the conditional or marginal likelihood. This involves considering the covariate values of all subjects that are at risk at the time when a failure occurs. The probability that the subject that failed had their observed set of covariate values is computed.

The risk set at a failure time consists of those subjects that fail or are censored at that time and those who survive beyond that time. As risk sets are computed for every distinct failure time, it should be noted that the combined risk sets may be considerably larger than the original data. If the data can be considered as coming from different strata such that $\lambda_0$ varies from strata to strata but $\beta$ remains constant, then nag_surviv_risk_sets (g12zac) will return a factor that indicates to which risk set/strata each member of the risk sets belongs rather than just to which risk set.

Given the risk sets the Cox proportional hazards model can then be fitted using a Poisson generalised linear model (nag_glm_poisson (g02gcc) with nag_dummy_vars (g04eac) to compute dummy variables) using Breslow’s approximation for ties (Breslow (1974)). This will give the same fit as nag_surviv_cox_model (g12bac). If the exact treatment of ties in discrete time is required, as given by Cox (1972b), then the model is fitted as a conditional logistic model using nag_condl_logistic (g11cac).

4 References

5 Parameters

1: order – Nag_OrderType

*Input*

*On entry:* the `order` parameter specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by `order = Nag_RowMajor`. See Section 2.2.1.4 of the Essential Introduction for a more detailed explanation of the use of this parameter.

*Constraint:* `order = Nag_RowMajor` or `Nag_ColMajor`.

2: `n` – Integer

*Input*

*On entry:* the number of data points, `n`.

*Constraint:* `n ≥ 2`.

3: `m` – Integer

*Input*

*On entry:* the number of covariates in array `z`.

*Constraint:* `m ≥ 1`.

4: `ns` – Integer

*Input*

*On entry:* the number of strata. If `ns > 0` then the stratum for each observation must be supplied in `isi`.

*Constraint:* `ns ≥ 0`.

5: `z[dim]` – const double

*Input*

*Note:* the dimension, `dim`, of the array `z` must be at least max(1, pdz × `m`) when `order = Nag_ColMajor` and at least max(1, pdz × `n`) when `order = Nag_RowMajor`.

If `order = Nag_ColMajor`, the (i, j)th element of the matrix Z is stored in `z[(j - 1) × pdz + i - 1]` and if `order = Nag_RowMajor`, the (i, j)th element of the matrix Z is stored in `z[(i - 1) × pdz + j - 1]`.

*On entry:* must contain the `n` covariates in column or row major order.

6: `pdz` – Integer

*Input*

*On entry:* the stride separating matrix row or column elements (depending on the value of `order`) in the array `z`.

*Constraints:*

- if `order = Nag_ColMajor`, `pdz ≥ n`;
- if `order = Nag_RowMajor`, `pdz ≥ m`.

7: `isz[m]` – const Integer

*Input*

*On entry:* indicates which subset of covariates are to be included in the model.

If `isz[j - 1] ≥ 1`, the `j`th covariate is included in the model.

If `isz[j - 1] = 0`, the `j`th covariate is excluded from the model and not referenced.

*Constraint:* `isz[j - 1] ≥ 0` and at least one value must be non-zero.

8: `ip` – Integer

*Input*

*On entry:* the number of covariates included in the model, `p`, as indicated by `isz`.

*Constraint:* `ip = the number of non-zero values of isz`.

9: `t[n]` – const double

*Input*

*On entry:* the vector of `n` failure censoring times.
10:  ic[n] – const Integer

*Input*

On entry: the status of the individual at time \( t \) given in \( t \).

- If \( ic[i - 1] = 0 \), indicates that the \( i \)th individual has failed at time \( t[i - 1] \).
- If \( ic[i - 1] = 1 \), indicates that the \( i \)th individual has been censored at time \( t[i - 1] \).

Constraint: \( ic[i - 1] = 0 \) or \( 1 \), for \( i = 1, 2, \ldots, n \).

11:  isi[dim] – const Integer

*Input*

Note: the dimension, \( dim \), of the array isi must be at least \( n \) when \( ns > 0 \) and at least 1 otherwise.

On entry: if \( ns > 0 \), the stratum indicators which also allow data points to be excluded from the analysis. If \( ns = 0 \), isi is not referenced.

- If \( isi[i - 1] = k \), indicates that the \( i \)th data point is in the \( k \)th stratum, where \( k = 1, 2, \ldots, ns \).
- If \( isi[i - 1] = 0 \), indicates that the \( i \)th data point is omitted from the analysis.

Constraint: if \( ns > 0 \), \( 0 \leq isi[i - 1] \leq ns \), for \( i = 1, 2, \ldots, n \).

12:  num – Integer *

*Output*

On exit: the number of values in the combined risk sets.

13:  ixsxmxn – Integer

*Output*

On exit: the factor giving the risk sets/strata for the data in \( x \) and \( id \). If \( ns = 0 \) or 1, \( ixsxmxn[i - 1] = l \) for members of the \( l \)th risk set. If \( ns > 1 \), \( ixsxmxn[i - 1] = (j - 1) \times nd + l \) for the observations in the \( l \)th risk set for the \( j \)th strata.

14:  nxs – Integer *

*Output*

On exit: the number of levels for the risk sets/strata factor given in ixsxmxn.

15:  x[dim] – double

*Output*

Note: the dimension, \( dim \), of the array \( x \) must be at least \( mnx \times ip \).

If order = Nag_ColMajor, the \((i,j)\)th element of the matrix \( X \) is stored in \( x[(j - 1) \times mnx + i - 1] \)
and if order = Nag_RowMajor, the \((i,j)\)th element of the matrix \( X \) is stored in \( x[(i - 1) \times ip + j - 1] \).

On exit: the first num rows contain the values of the covariates for the members of the risk sets.

16:  mnx – Integer

*Input*

On entry: the first dimension of the array \( x \) and the dimension of the arrays ixsxmxn and \( id \) as declared in the function from which nag_surviv_risk_sets (g12zac) is called.

Constraint: \( mnx \) must be sufficiently large for the arrays to contain the expanded risk sets. The size will depend on the pattern of failures times and censored times. The minimum value will be returned in num unless the routine exits with fail.code = NE_INT.

17:  id[mnx] – Integer

*Output*

On exit: indicates if the member of the risk set given in \( x \) failed. \( id[i - 1] = 1 \) if the member of the risk set failed at the time defining the risk set and \( id[i - 1] = 0 \) otherwise.

18:  nd – Integer *

*Output*

On exit: the number of distinct failure times, i.e., the number of risk sets.

19:  tp[n] – double

*Output*

On exit: \( tp[i - 1] \) contains the \( i \)th distinct failure time for \( i = 1, 2, \ldots, nd \).
20: \textbf{irs[n]} – Integer \hspace{1cm} \textit{Output}

On exit: indicates rows in \textbf{x} and elements in \textbf{ixs} and \textbf{id} corresponding to the risk sets. The first risk set corresponding to failure time \textbf{tp[0]} is given by rows 1 to \textbf{irs[0]}. The \textit{lth} risk set is given by rows \textbf{id[\textit{l}-2]} + 1 to \textbf{id[\textit{l}-1]} for \textit{l} = 1, 2, \ldots, \textbf{nd}.

21: \textbf{fail} – NagError * \hspace{1cm} \textit{Input/Output}

The NAG error parameter (see the Essential Introduction).

6 Error Indicators and Warnings

\textbf{NE_INT}

On entry, \textbf{n} = \textit{value}.
Constraint: \textbf{n} \geq 2.

On entry, \textbf{pdz} = \textit{value}.
Constraint: \textbf{pdz} > 0.

On entry, element \textit{value} of \textbf{isi} is not valid.
On entry, element \textit{value} of \textbf{ic} is not equal to 0 or 1.
On entry, element \textit{value} of \textbf{isz} < 0.
On entry, \textbf{ns} = \textit{value}.
Constraint: \textbf{ns} \geq 0.

On entry, \textbf{m} = \textit{value}.
Constraint: \textbf{m} \geq 1.

\textbf{NE_INT_2}

On entry, \textbf{pdz} = \textit{value}, \textbf{n} = \textit{value}.
Constraint: \textbf{pdz} \geq \textbf{n}.

On entry, \textbf{pdz} = \textit{value}, \textbf{m} = \textit{value}.
Constraint: \textbf{pdz} \geq \textbf{m}.

\textbf{NE_INT_ARRAY_ELEM_CONS}

\textbf{mxn} is too small: min value = \textit{value}.
On entry, there are not \textbf{ip} values of \textbf{isz} > 0.

\textbf{NE_ALLOC_FAIL}

Memory allocation failed.

\textbf{NE_BAD_PARAM}

On entry, parameter \textit{value} had an illegal value.

\textbf{NE_INTERNAL_ERROR}

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

7 Accuracy

Not applicable.
8 Further Comments

When there are strata present, i.e., $ns > 1$, not all the $nxs$ groups may be present.

9 Example

The data are the remission times for two groups of leukemia patients (see page 242 of Gross and Clark (1975)). A dummy variable indicates which group they come from. The risk sets are computed using `nag_surviv_risk_sets (g12zac)` and the Cox’s proportional hazard model is fitted using `nag_condl_logistic (g11cac)`.
