**nag_ip_bb (h02bbc)**

1. **Purpose**

*nag_ip_bb (h02bbc)* solves ‘zero-one’, ‘general’, ‘mixed’ or ‘all’ integer linear and quadratic programming problems using a branch and bound method. The function may also be used to find either the first integer solution or the optimum integer solution. It is not intended for large sparse problems.

2. **Specification**

```c
#include <nag.h>
#include <nagh02.h>
void nag_ip_bb(Integer n, Integer m, double a[], Integer tda,
                double bl[], double bu[], Boolean intvar[],
                double cvec[], double h[], Integer tdh,
                void (*qphess)(Integer n, Integer jthcol, double h[],
                               Integer tdh, double x[], double hx[],
                               Nag_Comm *comm),
                double x[], double *obj, Nag_H02_Opt *options,
                Nag_Comm *comm, NagError *fail)
```

3. **Description**

*nag_ip_bb* is capable of solving certain types of integer programming (IP) problems using a branch and bound (BB) method, see Taha (1987). In order to describe these types of integer programs and to briefly state the BB method, we define the following problem.

\[
\begin{align*}
\text{minimize} & \quad f(x) \\
\text{subject to} & \quad l \leq \begin{bmatrix} x \\ Ax \end{bmatrix} \leq u,
\end{align*}
\]

where \(A\) is an \(m\) by \(n\) matrix and \(f(x)\) may be specified in a variety of ways depending upon the particular problem to be solved. The available forms for \(f(x)\) are listed in Table 1 below. For the moment, however, we assume that \(f(x) = c^T x\) so that (1) is a linear programming (LP) problem.

If, in (1), it is required that some (or all) of the variables take integer values, then the integer program is of type mixed (or all) general IP problem. If, additionally, the integer variables are restricted to take only 0-1 values (i.e., \(l_j = 0\) and \(u_j = 1\)) then the integer program is of type mixed (or all) zero-one IP problem. *nag_ip_bb* does not treat the all integer or zero-one cases specially; therefore, since the mixed integer general IP case is the most general, we shall refer to (1), together with whatever integrality restrictions are applied, as a mixed integer linear programming (MILP) problem, with the assumption that the special cases are included in this.

The BB method applies directly to these integer programs. The general idea of BB is to solve the problem without the integrality restrictions as an LP problem (first or root node). If in the optimal solution an integer variable \(x_k\) takes a non-integer value \([x_k]\), two LP sub-problems or nodes are created by branching, imposing \(x_k \leq [x_k]\) and \(x_k \geq [x_k] + 1\) respectively, where \([x_k]\) denotes the integer part of \(x_k\). This method of branching continues until the first integer solution (bound) is obtained. The hanging nodes are then solved and investigated in order to prove the optimality of the solution. The algorithm is described in more detail in Section 7).

The same method may also be applied when the objective function \(f(x)\) takes other forms. An important assumption for the method to be theoretically valid is that each sub-problem is solved to global optimality. This is the case when, for example, \(f(x)\) is a quadratic function which has a positive (semi-)definite Hessian. For such \(f(x)\) the sub-problems of the BB search are quadratic programming (QP) problems, which can, in principle, be solved to global optimality. With a quadratic objective function, the problem becomes a mixed integer quadratic programming (MIQP) problem.
nag_ip_bb is able to solve problems in which \( f(x) \) is a linear or quadratic function, defined in a variety of ways as described in Table 1 below. The sub-problems are solved using the algorithm of nag_opt_qp (e04nfc).

</table>

Table 1

3.1. Suitability of BB Method for MIQP Problems

The BB method is applicable to an IP problem whenever the global optimum may reliably be found for each sub-problem, and this is theoretically true for an MILP problem. However, this may not be true for an MIQP problem in which the Hessian is not positive (semi-)definite; in such a case the sub-problems may have solutions which are locally but not globally optimal and, in general, it is not possible to ensure that a QP sub-problem solver will always find the global optimum when local optima are present. For problems of type MIQP3 and MIQP4, it is a consequence of the way the Hessian is defined that it must be positive (semi-)definite, but no such guarantee holds for problems of type MIQP1 or MIQP2.

nag_ip_bb does not check if the Hessian is positive (semi-)definite. This provides for the possibility that the user has special knowledge about the problem, for example that an indefinite Hessian is positive (semi-)definite on the feasible region defined by the problem constraints (in which case the problem has no local optima). Alternatively, the user may wish to use nag_ip_bb as a heuristic, with the understanding that if a solution is obtained, it may not be the true global optimum of the MIQP problem, or that no solution might be found even though one does exist. If the user wishes to check whether the Hessian of a problem of type MIQP1 or MIQP2 is positive (semi-)definite, and therefore whether any solution obtained can be relied upon, one way this may be achieved is to analyse its eigenvalues (for example using nag_real_symm_eigenvalues (f02aac)): the Hessian is positive semi-definite if and only if all of its eigenvalues are \( \geq 0 \).

3.2. Maximization Problems

nag_ip_bb attempts to solve a minimization problem of the form (1) (together with the integrality requirements). In principle, a maximization problem can be solved by minimizing \(-f(x)\), i.e., reversing the sign of the objective function. This is always valid in the case of an MILP problem, as long as the resulting problem is unbounded, and simply involves reversing the signs of the coefficients of \( c \) (the elements of the input parameter array cvec, see Section 4). In the case of an MIQP problem some care must be taken since reversing the sign of a positive (semi-)definite Hessian will make it negative (semi-)definite and vice-versa. Recall that the theoretical validity of the BB method, applied to an MIQP problem, effectively requires that the Hessian be positive (semi-)definite on the feasible region defined by the problem constraints.

Assuming these considerations to be taken into account, a maximization problem of type MIQP1 can be solved by reversing the signs of the elements of \( H \); type MIQP2 problems require the signs of the coefficients of \( c \) to be reversed also. Problem types MIQP3 and MIQP4 have a positive (semi-)definite Hessian by definition, so it would not normally make sense to solve these as maximization problems. Hence, nag_ip_bb does not allow the user to reverse the sign of the quadratic objective term for these problem types.

4. Parameters

\( n \)

Input: \( n \), the number of variables.
Constraint: \( n > 0 \).

\( m \)

Input: \( m \), the number of general linear constraints.
Constraint: \( m \geq 0 \).
a[m][tda]
Input: the \( i \)th row of \( a \) must contain the coefficients of the \( i \)th general linear constraint, for \( i = 1, 2, \ldots, m \).
If \( m = 0 \) then the array \( a \) is not referenced and may be set to the null pointer.

\( tda \)
Input: the second dimension of the array \( a \) as declared in the function from which \texttt{nag_ip_bb} is called.
Constraint: \( tda \geq n \) if \( m > 0 \).

\( bl[n+m] \)
\( bu[n+m] \)
Input: \( bl \) must contain the lower bounds and \( bu \) the upper bounds, for all the constraints in the following order. The first \( n \) elements of each array must contain the bounds on the variables, and the next \( m \) elements the bounds for the general linear constraints (if any).
To specify a non-existent lower bound (i.e., \( l_j = -\infty \), set \( bl[j-1] \leq -\text{inf\_bound} \), and to specify a non-existent upper bound (i.e., \( u_j = +\infty \), set \( bu[j-1] \geq \text{inf\_bound} \), where \text{inf\_bound} is one of the optional parameters (default value \( 10^{20} \), see Section 8.2). To specify the \( j \)th constraint as an equality, set \( bl[j-1] = bu[j-1] = \beta \), say, where \( \beta < \text{inf\_bound} \).
Constraint: \( bl[j] \leq bu[j] \), for \( j = 0, 1, \ldots, n+m-1 \).

\( \text{intvar}[n] \)
Input: indicates which are the integer variables in the problem. For example, if \( x_j \) is an integer variable then \( \text{intvar}[j-1] \) must be set to 1, and 0 otherwise. The degenerate case, in which all elements of \( \text{intvar} \) are zero, is allowed. In this case, \texttt{nag_ip_bb} solves a single LP or QP problem (depending on the problem type as specified by the optional parameter \( \text{prob} \), see Section 8.2).
Constraint: \( \text{intvar}[j] = 0 \) or 1 for \( j = 0, 1, \ldots, n-1 \).

\( \text{cvec}[n] \)
Input: the coefficients \( c_j \) of the explicit linear term of the objective function when the problem is of type MILP, MIQP2 or MIQP4. The default problem type is MILP; other problem types can be specified using the optional parameter \( \text{prob} \), see Section 8.2.
If the problem is of type MIQP1 or MIQP3, \( \text{cvec} \) is not referenced and may be set to the null pointer.

\( h[n][tdh] \)
Input: \( h \) may be used to store the quadratic term \( H \) of the MIQP objective function if desired. The elements of \( h \) are accessed only by the function \( \text{qphess} \); thus, \( h \) is not accessed if the problem is of the type MILP (the default) and may be set to the null pointer.
The number of rows of \( h \) is denoted by \( n_H \) and its default value is equal to \( n \). (The optional parameter \( hrows \) may be used to specify a value of \( n_H < n \); see Section 8.2).
If the problem is of type MIQP1 or MIQP2, the first \( n_H \) rows and columns of \( h \) must contain the leading \( n_H \) by \( n_H \) rows and columns of the symmetric Hessian matrix. Only the diagonal and upper triangular elements of the leading \( n_H \) rows and columns of \( h \) are referenced. The remaining elements need not be assigned.
For problems of type MIQP3 and MIQP4, the first \( n_H \) rows of \( h \) must contain an \( n_H \) by \( n \) upper trapezoidal factor of the Hessian matrix. The factor need not be of full rank, i.e., some of the diagonals may be zero. However, as a general rule, the larger the dimension of the leading non-singular sub-matrix of \( H \), the fewer iterations will be required. Elements outside the upper trapezoidal part of the first \( n_H \) rows of \( H \) are assumed to be zero and need not be assigned.
In some cases, the user need not use \( h \) to store \( H \) explicitly (see the specification of function \( \text{qphess} \) below).

\( tdh \)
Input: the second dimension of the array \( h \) as declared in the function from which \texttt{nag_ip_bb} is called.
Constraint: \( tdh \geq n \) or at least the value of the optional parameter \( hrows \) if it is set. This constraint is enforced only for problems of type MIQP in which the \( \text{qphess} \) parameter is null.
qphess

In general, the user need not provide a version of qphess, because a ‘default’ function is included in the NAG C Library. If the default function is required then the NAG defined null function pointer, NULLFN, should be supplied in the call to nag_ip_bb. The algorithm of nag_ip_bb requires only the product of $H$ and a vector $x$; and in some cases the user may obtain increased efficiency by providing a version of qphess that avoids the need to define the elements of the matrix $H$ explicitly.

qphess is not referenced for problems of type MILP (the default), in which case qphess should be replaced by NULLFN.

The specification of qphess is:

```c
void qphess(Integer n, Integer jthcol, double h[], Integer tdh, double x[],
            double hx[], Nag_Comm *comm)

n
Input: $n$, the number of variables.

jthcol
Input: jthcol specifies whether or not the vector $x$ is a column of the identity matrix. If $jthcol = j > 0$, then the vector $x$ is the $j$th column of the identity matrix, and hence $Hx$ is the $j$th column of $H$, which can sometimes be computed very efficiently and qphess may be coded to take advantage of this. However special code is not necessary because $x$ is always stored explicitly in the array x. If $jthcol = 0$, $x$ has no special form.

h[n*tdh]
Input: the matrix $H$ of the QP objective function. The matrix element $H_{ij}$ is contained in $h[(i-1) * tdh + j - 1]$ for $i = 1, 2, \ldots, n$ and $j = 1, 2, \ldots, n$. In some situations, it may be desirable to compute $Hx$ without accessing h - for example, if $H$ is sparse or has special structure. (This is illustrated in the function qphess in the example program in Section 13.) The parameters h and tdh may then refer to any convenient array.

tdh
Input: the second dimension of the array h in the calling program.

x[n]
Input: the vector $x$.

hx[n]
Output: the product $Hx$.

comm
Pointer to structure of type Nag_Comm; the following members are relevant to qphess.

flag – Integer
Input: qphess is called with comm -> flag set to a non-negative number. Output: if qphess resets comm -> flag to some negative number then nag_ip_bb will terminate immediately with the error indicator NE_USER_STOP. If fail is supplied to nag_ip_bb, fail.errnum will be set to the user’s setting of comm -> flag.

first – Boolean
Input: will be set to TRUE on the first call to qphess and FALSE for all subsequent calls.

nf – Integer
Input: the number of calls made to qphess including the current one.
Note: `qphess` should be tested separately before being used in conjunction with `nag_ip_bb`. The input arrays `h` and `x` must not be changed by `qphess`.

- **x[n]**: Input: an initial estimate of the solution of the first sub-problem (the root node problem as described in Section 3).
  
  If optional parameter `branch_dir = Nag_Branch_InitX` (which is not the default value), then the initial values in `x` of the integer variables influence the branching procedure in the BB algorithm. Typically, an estimate of the values of the integer variables in the IP solution would be provided in this case. See Section 8.2 for details.

  Output: with `fail.code = NE_NOERROR`, `x` contains a solution which will be an estimate of either the optimum integer solution or the first integer solution, depending on the value of optional parameter `first_sol`. If `fail.code = NW_MIP_MAX_NODES_INT_SOL`, `NW_MIP_MAX_DEPTH_INT_SOL`, `NW_MIP_MAX_ITER_INT_SOL`, or `NE_MIP_HESS_TOO_BIG_INT_SOL` then `x` contains a solution which may not be the optimal IP solution because `nag_ip_bb` was unable to investigate all of the nodes. See Section 9 for more details.

- **objf**: Output: with `fail.code = NE_NOERROR`, `NW_MIP_MAX_NODES_INT_SOL`, `NW_MIP_MAX_DEPTH_INT_SOL`, `NW_MIP_MAX_ITER_INT_SOL`, or `NE_MIP_HESS_TOO_BIG_INT_SOL`, `objf` contains the value of the objective function for the IP solution.

- **options**: Input/Output: a pointer to a structure of type `Nag_H02_Opt` whose members are optional parameters for `nag_ip_bb`. These structure members offer the means of adjusting some of the parameter values of the algorithm and on output will supply further details of the results. A description of the members of `options` is given below in Section 8.
  
  The `options` structure also allows names to be assigned to the variables and constraints of the problem, which are then used in solution output. In particular, if the problem is defined by an MPSX file, the function `nag_ip_mps_read (h02bbc)` may be used to read the file, and to store the variable and constraint names in `options` for use by `nag_ip_bb`.
  
  If any of these optional parameters are required then the structure `options` should be declared and initialised by a call to `nag_ip_init (h02xcc)` and supplied as an argument to `nag_ip_bb`. However, if the optional parameters are not required the NAG defined null pointer, `H02_DEFAULT`, can be used in the function call.

- **comm**: Input/Output: structure containing pointers for communication to the user-supplied function, `qphess`, and the optional user-defined printing function. See the description of `qphess` and Section 8.3.1 for details. If the user does not need to make use of this communication feature the null pointer `NAGCOMM_NULL` may be used in the call to `nag_ip_bb`; `comm` will then be declared internally for use in calls to user-supplied functions.

- **fail**: The NAG error parameter, see the Essential Introduction to the NAG C Library.
  
  Users are recommended to declare and initialise `fail` and set `fail.print = TRUE` for this function.
4.1. Description of Printed Output

Intermediate and final results are printed out by default. The level of printed output can be controlled by the user with the structure member `options.print_level` (see Section 8.2). The default print level of `Nag_Soln_Iter` provides a single line of output at the end of each node and the final IP result. If `nag_ip_bb` fails to find an IP solution, the final solution printed will be the original LP or QP (`root node`) solution. This section describes the default printout produced by `nag_ip_bb`.

The following line of summary output is produced at the end of every node. It gives the outcome of forcing an integer variable with a non-integer value to take a value within its specified lower and upper bounds.

- **Node No** is the current node number of the BB tree being investigated.
- **Parent Node** is the parent node number of the current node.
- **Obj Value** is the final objective function value. If a node does not have a feasible solution then Infeasible is printed instead of the objective function value. If a node whose optimum solution exceeds the best integer solution so far is encountered (i.e., it does not pay to explore the sub-problem any further), then its objective function value is printed together with a CO (Cut Off).
- **Varbl Chosen** is the index of the integer variable chosen for branching.
- **Value Before** is the non-integer value of the integer variable chosen.
- **Lower Bound** is the lower bound value that the integer variable is allowed to take.
- **Upper Bound** is the upper bound value that the integer variable is allowed to take.
- **Value After** is the value of the integer variable after the current optimization.
- **Depth** is the depth of the BB tree at the current node.

The final printout includes a listing of the status of each variable and constraint.

- **Varbl** gives the name of variable $j$, for $j = 1, 2, \ldots, n$. If an options structure is supplied to `nag_ip_bb`, and the `crnames` member is assigned to an array of variable and constraint names (see Section 8.2 for details), the name supplied in `crnames[j - 1]` is assigned to the $j$th variable. Otherwise, a default name is assigned to the variable.
- **State** gives the state of the variable (FR if neither bound is in the working set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound, TF if temporarily fixed at its current value). If Value lies outside the upper or lower bounds by more than the feasibility tolerance, State will be ++ or -- respectively.
- **Value** is the value of the variable at the final iteration.
- **Lower Bound** is the lower bound $l_j$ specified for the variable. (None indicates that $l_j \leq -\text{inf_bound}$, where inf_bound is the optional parameter.) The bound is that imposed at the node which provided the IP solution. (If no IP solution was found, the bound is that supplied by the user in bl.)
- **Upper Bound** is the upper bound $u_j$ specified for the variable. (None indicates that $u_j \geq \text{inf_bound}$.) The bound is that imposed at the node which provided the IP solution. (If no IP solution was found, the bound is that supplied by the user in bu.)
- **Lagr Mult** is the value of the Lagrange multiplier for the associated bound constraint. This will be zero if State is FR or TF. If $x$ is optimal, the multiplier should be non-negative if State is LL, and non-positive if State is UL.
- **Residual** is the difference between the variable Value and the nearer of its bounds $l_j$ and $u_j$. 

The following line of summary output is produced at the end of every node. It gives the outcome of forcing an integer variable with a non-integer value to take a value within its specified lower and upper bounds.
The meaning of the printout for general constraints is the same as that given above for variables, with ‘variable’ replaced by ‘constraint’, \( n \) replaced by \( m \), \( \text{crnames} [j - 1] \) replaced by \( \text{crnames} [n + j - 1] \), \( l_j \) and \( u_j \) replaced by \( l_{n+i} \) and \( u_{n+i} \) respectively, and with the following change in the heading:

\[ \text{Constr} \]

\text{Constr} gives the name of the constraint.

Numerical values are output with a fixed number of digits; they are not guaranteed to be accurate to this precision.

### 5. Comments

A list of possible error exits and warnings from \texttt{nag_ip_bb} is given in Section 9. The accuracy of \texttt{nag_ip_bb} is considered in Section 10, where further comments may also be found.

### 6. Example 1

To solve the integer programming problem:

\[
\begin{align*}
\text{maximize} & \quad F(x) = 3x_1 + 4x_2 \\
\text{subject to} & \quad x_1 \geq 0 \\
& \quad x_2 \geq 0 \\
\text{and to the general constraints} & \quad \\
& \quad 2x_1 + 5x_2 \leq 15 \\
& \quad 2x_1 - 2x_2 \leq 5 \\
& \quad 3x_1 + 2x_2 \geq 5
\end{align*}
\]

where \( x_1 \) and \( x_2 \) are integer variables. The initial point, which is feasible, is

\[
x_0 = (1, 1)^T,
\]

and \( F(x_0) = 7 \). The optimal solution is

\[
x^* = (2, 2)^T,
\]

and \( F(x^*) = 14 \). Note that maximizing \( F(x) \) is equivalent to minimizing \( -F(x) \).

This example shows the simple use of \texttt{nag_ip_bb} where default values are used for all optional parameters. An example showing the use of optional parameters is given in Section 13. There is one example program file, the main program of which calls both examples. The main program and example 1 are given below.

Exit from branch and bound tree search after 9 nodes.
Optimal IP solution found.

Final IP objective value = -1.4000000e+01

7. Further Description

This section provides further information about the BB algorithm used by nag_ip_bb. This, and possibly the next section, Section 8, may be omitted if the more sophisticated features of the algorithm and software are not currently of interest.

Further descriptions of the BB algorithm may be found in Dakin (1965) and Mitra (1973).

7.1. Overview

As outlined in Section 3, the essence of the BB algorithm is to form a ‘tree’ of sub-problems which are relatively easy to solve. The initial sub-problem, the root node of the tree, is a relaxation of the IP problem, in that it is the IP problem with the integer restrictions removed. When that has been solved, two child sub-problems or nodes are formed by selecting an integer variable $x_k$ which in the
solution to the relaxed problem takes a non-integer value $x_k^*$, and branching on that variable, i.e., imposing $x_k \leq [x_k^*]$ for one node and $x_k \geq [x_k^*] + 1$ for the other, where $[x_k^*]$ denotes the integer part of $x_k^*$. One of these nodes is then solved. At this point, either a further branching operation is carried out from the node just solved, creating two new unsolved nodes (one of which is solved next), or the remaining unsolved child node is solved. Continuing in this way, the tree is developed – at each stage selecting an unsolved node to solve, or a solved node to branch from. The selection of the node and, in the case of a branching operation, the selection of the variable to branch on, is considered further in Section 7.2.

The mechanism for forming the nodes on branching simply involves adjusting the lower or upper bound on the branching variable. Note that as the tree is descended, each child node inherits any bound adjustments made to its parent node, and so a child node is always more constrained than its parent.

If the procedure described above is continued, eventually a child must be created for which all of its integer variables are fixed at integer values, or which is infeasible. If the latter is true then the search down that branch of the tree may be terminated since any children of that node must also be infeasible (the child is always more constrained than the parent). If the former is true then we have an integer feasible solution for the IP problem, which may or may not be the optimum integer solution. For some applications of IP, it is sufficient to obtain any integer feasible solution and the search may terminate here, but usually the search must be continued, either to find a better integer solution, or to confirm that the optimal integer solution has been found. In nag_ip_bb the optional parameter first_soln may be set to TRUE to request termination at the first integer solution (the default value is FALSE, see Section 8.2).

Assuming that the optimal integer solution is required, the rest of the tree must be searched. The efficiency of the method relies on not having to examine every node of the tree which could, potentially, be formed by applying the procedure as described above. The method incorporates features which have the effect of eliminating certain portions of the tree from the search. As already explained, the search is terminated along a particular branch on encountering an infeasible node. Similarly, once an integer solution has been found, this can be used to eliminate parts of the search tree as follows. Suppose an integer feasible solution $x^+$ has been found, with an associated objective function value $f(x^+)$. Now suppose during the search of the remainder of the tree, a node is encountered, whose objective function value exceeds $f(x^+)$. In this case there is no need to examine any further down that branch of the tree since any children of that node will also have objective function values which exceed $f(x^+)$. The quantity $f(x^+)$ therefore acts as a bound on the optimal integer solution. This bound may be refined as better integer solutions are found. Finally, if an integer solution is found before all integer variables have been fixed by the branching process, simply because the unfixed integer variables happen to have integer values at the solution of a particular node, there is again no need to search further along that branch of the tree. Termination of the search at a node, whether through finding an integer solution there, detecting infeasibility, or bounding it based on a known integer solution, is known as fathoming the node.

7.2. Selection of Node and Branching Variable

Since each branching operation generates two unsolved nodes (sub-problems), at a typical stage of the algorithm there will be a number of nodes which are either unsolved or which have been solved but have not yet been branched from. Therefore, when a node has been solved there is a choice to be made as to which node should be solved next, and this will either be an existing, unsolved node, or one which will be created by a branching operation.

If a node is selected to be branched from, there is a further choice to be made and that is the integer variable to be branched on.

Within nag_ip_bb these choices are controlled by the optional parameters nodsel, which controls node selection, and varsel, which controls branching variable selection. The default node selection behaviour is to choose the node with lowest objective value, if it has been solved, or lowest parent objective value if it is unsolved. By default the branching variable chosen is that with the smallest index in $x$, selected from those integer variables taking non-integer values at the solution of the sub-problem being branched from. Details of the available options are given in Section 8.2.

These choices can help to improve the efficiency of the BB algorithm since they particularly influence how quickly the first integer feasible solution is obtained and its quality. A good integer solution
obtained early in the search can eliminate a large portion of the remaining tree, by means of the bounding operation described in Section 7.1.1. Unfortunately, there is no single strategy for making such choices which can be applied successfully to all IP problems – the best strategy is highly problem dependent and is usually obtained by experimentation.

7.3. Further Reducing the Size of the BB Search Tree

In addition to considering variations in the node and variable selection strategies, the user may also consider setting some other parameters to help to reduce the number of nodes searched. Recall from Section 7.1 that once the algorithm has found an IP solution, the objective function value associated with this is used as a bound to eliminate parts of the tree. Similarly, if the user knows from the outset a strict upper bound on the optimal solution, perhaps as a result of solving a related, more constrained problem, or obtained through analytical means, this may be supplied to nag_ip_bb as the optional parameter int_obj_bound. This will be used by nag_ip_bb in the same way as a bound obtained by finding an IP solution except that it can be used to eliminate parts of the tree even before an integer solution is found.

Another parameter which the user might consider setting to reduce the size of the tree is soln_tol. Again this is related to the bounding process, and applies when an integer solution has been found. When searching the remainder of the tree, instead of setting the bound to \( f(x^+) \), the objective function value associated with the integer solution most recently found, nag_ip_bb sets the bound to \( f(x^+) - \text{soln}_\text{tol} \). This means that integer solutions with objective values within \( \text{soln}_\text{tol} \) of any integer solution already found, can not themselves be found. The idea here is to allow the user to avoid further search for solutions which are not substantially better (as measured by \( \text{soln}_\text{tol} \)) than the best solution found so far. Of course, a sensible choice for the value of \( \text{soln}_\text{tol} \) relies on the user’s knowledge of the problem and requirements on the solution.

Further details of the optional parameters int_obj_bound and soln_tol are given in Section 8.2.

Finally, a very important factor which can have a large impact on the size of the search tree is the way the problem is modelled. Often, there is more than one way to formulate a problem as an IP model. A general aim is that the feasible region of the relaxed IP problem should be as close as possible to that of the IP problem itself. This has the effect of generating tight bounds in the BB procedure. Note that in order to achieve this aim, it may be necessary to introduce further constraints, which do not alter the IP solution but which help to reduce the feasible region of the sub-problems. This is in contrast to standard LP, for example, in which fewer constraints are generally considered to be associated with an easier problem. There is of course a balance to be struck since adding constraints to an IP problem will make the sub-problems harder to solve, despite, it is hoped, reducing the size of the tree. See Williams (1993) for more information on formulating IP models.

8. Optional Parameters

A number of optional input and output parameters to nag_ip_bb are available through the structure argument options, type Nag_H02_Opt. A parameter may be selected by assigning an appropriate value to the relevant structure member; those parameters not selected will be assigned default values. If no use is to be made of any of the optional parameters the user should use the NAG defined null pointer, H02_DEFAULT, in place of options when calling nag_ip_bb; the default settings will then be used for all parameters.

Before assigning values to options directly the structure must be initialised by a call to the function nag_ip_init (h02xxc). Values may then be assigned to the structure members in the normal C manner.

Option settings may also be read from a text file using the function nag_ip_read (h02xyc) in which case initialisation of the options structure will be performed automatically if not already done. Any subsequent direct assignment to the options structure must not be preceded by initialisation.

If assignment of functions and memory to pointers in the options structure is required, then this must be done directly in the calling program; they cannot be assigned using nag_ip_read (h02xyc).
8.1. Optional Parameter Checklist and Default Values

For easy reference, the following list shows the members of options which are valid for nag_ip_bb together with their default values where relevant. The number $\epsilon$ is a generic notation for machine precision (see nag_machine_precision (X02AJC)).

- **prob** – Nag_MIP_ProbType Default = Nag_MILP
  Input: specifies the type of objective function to be minimized during the optimality phase. The following are the five possible values of prob and the size of the arrays h and cvec that are required to define the objective function:

  - Nag_MILP: $h$ not referenced, $cvec[n]$;
  - Nag_MIQP1: $h[n][tdh]$ symmetric, $cvec$ not referenced;
  - Nag_MIQP2: $h[n][tdh]$ symmetric, $cvec[n]$;
  - Nag_MIQP3: $h[n][tdh]$ upper trapezoidal, $cvec$ not referenced;

  Constraint: options.prob = Nag_MILP, Nag_MIQP1, Nag_MIQP2, Nag_MIQP3 or Nag_MIQP4.

- **list** – Boolean Default = TRUE
  Input: if options.list = TRUE the parameter settings in the call to nag_ip_bb will be printed.

- **print_level** – Nag_PrintType Default = Nag_Soln_Iter
  Input: the level of results printout produced by nag_ip_bb. The following values are available.

  - Nag_NoPrint: No output.
  - Nag_Soln: The final IP solution.
  - Nag_Soln_Root: The root node and final IP solution.

8.2. Description of Optional Parameters

- **prob** – Nag_MIP_ProbType Default = Nag_MILP
  Input: specifies the type of objective function to be minimized during the optimality phase.

- **list** – Boolean Default = TRUE
  Input: if options.list = TRUE the parameter settings in the call to nag_ip_bb will be printed.

- **print_level** – Nag_PrintType Default = Nag_Soln_Iter
  Input: the level of results printout produced by nag_ip_bb. The following values are available.
**nag_ip_bb**

Nag_Iter  
One line of output for each node investigated.

Nag_Soln_Iter  
The final IP solution and one line of output for each node.

Nag_Soln_Root_Iter  
The root node and final IP solution and one line of output for each node.

Details of each level of results printout are described in Section 8.3.

Constraint: options.print_level = Nag_NoPrint, Nag_Soln, Nag_Soln_Root, Nag_Iter, Nag_Soln_Iter or Nag_Soln_Root_Iter.

outfile - char[80]  
Default = stdout

Input: the name of the file to which results should be printed. If options.outfile[0] = '\0' then the stdout stream is used.

print_fun - pointer to function  
Default = NULL

Input: printing function defined by the user; the prototype of print_fun is
void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm);

See Section 8.3.1. below for further details.

max_iter - Integer  
Default = max(50,5(n+m))

Input: the limit on the number of iterations for each node.
Constraint: options.max_iter ≥ 0.

max_nodes - Integer  
Default = ALL_NODES

Input: the maximum number of nodes that are to be searched in order to find a solution (optimum integer solution). If max_nodes is not set, or is set equal to the symbol ALL_NODES, and the optional parameter first_soln = FALSE (the default), then the BB tree search is continued until all the nodes have been investigated.
Constraint: options.max_nodes > 0 or options.max_nodes = ALL_NODES.

first_soln - Boolean  
Default = FALSE

Input: specifies whether to terminate the BB tree search after the first integer solution (if any) is obtained. If first_soln = TRUE then the BB tree search is terminated at node k say, which contains the first integer solution. For optional parameter max_nodes ≠ ALL_NODES this applies only if k ≤ max_nodes.

max_depth - Integer  
Default = max(10,3n/2)

Input: the maximum depth of the BB tree used for branch and bound.
Constraint: options.max_depth ≥ 2.

int_tol – double  
Default = 10^{-5}

Input: the integer feasibility tolerance; i.e., an integer variable is considered to take an integer value if its violation does not exceed int_tol. For example, if the integer variable x_j is of order unity then x_j is considered to be integer if (1−int_tol) ≤ x_j ≤ (1+int_tol).
Constraint: options.int_tol > 0.0.

int_obj_bound – double  
Default = 10^{20}

Input: specifies an initial bound on the optimum integer solution. The user should supply a value for this parameter only if a valid strict upper bound for the IP problem is available. Supplying too small a value will result in nag_ip_bb not finding an IP solution. If a valid value is provided then this may help to reduce the number of nodes searched in the BB tree (see Section 7.3).

The default value, 10^{20}, is equivalent to no such bound being available.

soln_tol – double  
Default = \sqrt{\epsilon}

Input: specifies a tolerance on the optimal IP solution, i.e., an IP solution returned by nag_ip_bb as optimal may have an objective function value which is as much as soln_tol greater than that associated with the true optimal IP solution. By setting soln_tol to a non-zero value, the size of the BB search tree may be reduced at the expense of obtaining a (possibly) inferior solution (see Section 7.3).
This parameter only takes effect after the first IP solution has been found. It therefore has no effect if optional parameter first_soll = TRUE and need not be taken into account when setting optional parameter int_obj_bound. Constraint: options.soll_tol ≥ 0.0.

nodel – Nag_Node_Selection

Input: specifies how nodes are selected during the BB tree search (see Section 7.2). The selection is made from those nodes which are still ‘active’, i.e., those which either have not yet been solved, or which have been solved but not yet branched from. If the node selected has not been solved then it will be solved next; otherwise, it is branched from and one of the resulting child nodes will be solved next. In the latter case, the choice of which child node is solved first is determined by the value of optional parameter branch_dir (see below). The possible values of nodel and their meanings are described below.

Nag_MinObj_Search selects the node with smallest objective function value. A node which has not yet been solved is assigned its parent’s objective function value as the basis for its selection.

Nag_Deep_Search selects the deepest node in the BB tree. When selecting a node for branching and there is more than one candidate at the deepest level, preference is given to the node which was solved earliest. This type of node selection is affected by the value of branch_dir (see below).

Nag_Broad_Search selects the shallowest node in the tree. This has the effect of searching across the tree (rather than down as for Nag_Deep_Search).

Nag_DepMinObj_Search as Nag_Deep_Search until the first integer solution is found and as Nag_MinObj_Search thereafter.

Nag_DepBroad_Search as Nag_Dep_search until the first integer solution is found and as Nag_Broad_Search thereafter.

Constraint: options.nodel = Nag_MinObj_Search, Nag_Deep_Search, Nag_Broad_Search, Nag_DepMinObj_Search or Nag_DepBroad_Search.

varsel – Nag_Var_Selection

Input: specifies how nag_ip_bb selects the variable to branch on, when an unbranched node has been chosen according to optional parameter nodel. Let x^* denote the solution associated with the selected node. Integer variables are scanned in order of their index in x, and any which are integral to within the optional tolerance parameter int_tol are ignored. The following values of varsel are available.

Nag_First_Int select the first integer variable x_i such that x_i^* is non-integer.

Nag_Nearest_Half select the integer variable x_i such that |x_i^* − [x_i^*]| is nearest to 0.5, where [x_i^*] denotes the integer part of x_i^*. That is, x_i is the integer variable such that x_i^* is farthest from having an integer value.

Nag_Use_Priority branch on the integer variable selected according to the set of priorities provided by the user in optional parameter priority (see below).

Constraint: options.varsel = Nag_First_Int, Nag_Nearest_Half or Nag_Use_Priority.

branch_dir – Nag_Branch_Direction

Input: specifies which node to solve first when two nodes are created by a branching operation. This option is unlikely to have much effect when optional parameter nodel = Nag_MinObj_Search or Nag_Broad_Search, since the overall order in which parts of the tree are examined will remain the same. However, when nodel = Nag_Deep_Search, branch_dir will influence the path taken by nag_ip_bb as the tree is descended. Similarly,
**NAG C Library Manual**

this parameter will affect the initial deep search when \( \text{nodsels} = \text{Nag}_\text{DeepMinObjSearch} \) or \( \text{Nag}_\text{DeepBroadSearch} \). The following values of \( \text{branch} \) are available.

- **Nag\textunderscore Branch\textunderscore Left** solve the ‘left’ node first, i.e., that which was formed by reducing the upper bound on the branching variable.

- **Nag\textunderscore Branch\textunderscore Right** solve the ‘right’ node first, i.e., that which was formed by increasing the lower bound on the branching variable.

- **Nag\textunderscore Branch\textunderscore InitX** branch according to the initial values of the integer variables, as supplied in the parameter \( x \) to \( \text{nag}_\text{ip}\_\text{bb} \). Let \( x^0 \) be the initial solution as supplied by the user, and let \( i \) be the index of the integer variable currently being branched on. Then if \( x^i_k \) is the nearest integer to \( x^0_k \) which satisfies the initial bounds on \( x \), \( \text{nag}_\text{ip}\_\text{bb} \) will first branch towards \( x^i_k \) and solve this sub-problem. This value of \( \text{branch} \) would be appropriate, in conjunction with a deep search (as defined by \( \text{nodsels} \)), if the user can provide in \( x \) a good estimate of an integer solution to the IP problem.

**Constraint:** \( \text{options.branch} = \text{Nag\textunderscore Branch\textunderscore Left}, \text{Nag\textunderscore Branch\textunderscore Right} \) or \( \text{Nag\textunderscore Branch\textunderscore InitX} \).

**priority** – double * Default = NULL

Input: if \( \text{varsel} = \text{Nag\textunderscore Use\textunderscore Priority} \) then for each integer variable \( x_i \), \( \text{priority}[i - 1] \) must contain the priority the variable should be given when \( \text{nag}_\text{ip}\_\text{bb} \) selects a variable to branch on (\( x_i \) is an integer variable if \( \text{intvar}[i - 1] = \text{TRUE} \), for \( i = 1, 2, \ldots, n \)). For example, if \( x_k \) and \( x_l \) are integer variables and \( \text{priority}[l - 1] > \text{priority}[k - 1] \), then variable \( x_l \) will be selected in preference to \( x_k \). Variables with equal priorities are selected according to their indices (i.e., \( x_k \) is selected if \( k < l \) and \( \text{priority}[k - 1] = \text{priority}[l - 1] \)).

With some problems of type MILP, setting \( \text{priority} \) to \( \text{cvec} \) might be effective, since the objective coefficient of a variable could be regarded as a measure of the importance of the variable in the problem.

If \( x_i \) is not an integer variable (i.e., \( \text{intvar}[i - 1] = \text{FALSE} \)), \( \text{priority}[i - 1] \) is not referenced. If optional parameter \( \text{nodsels} \neq \text{Nag\textunderscore Use\textunderscore Priority} \) then \( \text{priority} \) is not referenced.

**feas_tol** – double Default = \( \sqrt{\epsilon} \)

Input: the maximum acceptable absolute violation in each constraint at a ‘feasible’ point (feasibility tolerance); i.e., a constraint is considered satisfied if its violation does not exceed \( \text{feas_tol} \).

**Constraint:** \( \text{options.feas_tol} > 0.0 \).

**inf_bound** – double Default = \( 10^{20} \)

Input: \( \text{inf_bound} \) defines the ‘infinite’ bound in the definition of the problem constraints. Any upper bound greater than or equal to \( \text{inf_bound} \) will be regarded as plus infinity (and similarly any lower bound less than or equal to \( -\text{inf_bound} \) will be regarded as minus infinity).

**Constraint:** \( \text{options.inf_bound} > 0.0 \).

**rank_tol** – double Default = \( 100\epsilon \)

This parameter is not used for problems of type MILP.

Input: \( \text{rank_tol} \) enables the user to control the condition number of the triangular matrix factor \( R \) which arises in solving a QP subproblem (see Section 7 of the documentation for \( \text{nag}_\text{qp}\_\text{qp} \) (e04nfc) for details). If \( p_i \) denotes the function \( p_i = \max\{|R_{11}|,|R_{22}|,\ldots,|R_{ii}|\} \), the dimension of \( R \) is defined to be smallest index \( i \) such that \( |R_{i+1,i+1}| \leq \text{rank_tol} \times |p_{i+1}| \).Constraint: \( 0.0 \leq \text{options.rank_tol} < 1.0 \).

**hrows** – Integer Default = 0 or \( n \)

Input: specifies \( n_H \), the number of rows of the quadratic term \( H \) of the QP objective function. For the default MILP problem type, \( \text{hrows} \) is not used and its value is set to zero. For MIQP problem types, the default value of \( \text{hrows} \) is \( n \), the number of variables. However, a value of \( \text{hrows} < n \) is appropriate for problems of type MIQP3 or MIQP4 when \( H \) is an upper
trapezoidal matrix with \( n_H \) rows. Similarly, \( \text{hrows} \) may be used to define the dimension of a leading block of non-zeros in the Hessian matrices for problems of type MIQP1 or MIQP2, in which case the last \( n \) – \( n_H \) rows and columns of \( H \) are assumed to be zero.

Constraint: \( 0 \leq \text{options.hrows} \leq n \).

**max_df** – Integer

Input: places a limit on the storage allocated for the triangular factor \( R \) of the reduced Hessian \( H_r \) of QP sub-problems (see Section 7 of the documentation for \text{nag_ipmip}_\text{ip} (\text{e04nfc}) for details). Ideally, \( \text{max_df} \) should be set slightly larger than the value of \( n_c \) (the number of rows and columns of \( H_r \)) expected at the solution. It need not be larger than \( m_n + 1 \), where \( m_n \) is the number of variables that appear nonlinearly in the quadratic objective function. For many problems it can be much smaller than \( m_n \).

For quadratic problems, a minimizer may lie on any number of constraints, so that \( n_c \) may vary between 1 and \( n \). The default value is therefore normally \( n \) but if the optional parameter \text{hrows} \) is specified then the default value of \text{max_df} \) is set to the value in \text{hrows} \).

Constraint: \( 1 \leq \text{options.max_df} \leq n \).

**crnames** – char \*

Input: if \text{crnames} is not NULL then it must point to an array of \( n+m \) character strings, with maximum string length 8, containing the names of the variables and constraints of the problem. Thus, \text{crnames}[j-1] \) contains the name of the \( j \)th variable, \( j = 1, 2, \ldots, n \), and \text{crnames}[n+i-1] \) contains the names of the \( i \)th constraint, \( i = 1, 2, \ldots, m \). If supplied, the names are used in the solution output (see Section 4.1 and Section 8.3).

If a problem is defined by an MPSX file, it may be read by calling \text{nag_ipmip}_\text{mpss_read} (\text{h02buc}) prior to calling \text{nag_ipmip}_\text{bb}. In this case, \text{nag_ipmip}_\text{mpss_read} (\text{h02buc}) may optionally be used to allocate memory to \text{crnames} \) and to read the variable and constraint names defined in the MPSX file into \text{crnames} \). In this case, the memory freeing function \text{nag_ipmip}_\text{free} (\text{h02zxz}) should be used to free the memory pointed to by \text{crnames} \) on return from \text{nag_ipmip}_\text{bb}. Users should not use the standard C function \text{free()} \) for this purpose.

**lower** – double *

Input: \( n+m \) values of memory will be automatically allocated by \text{nag_ipmip}_\text{bb} \) and this is the recommended method of use of \text{options.lower}. However a user may supply memory from the calling program.

Output: the lower bounds imposed at the point returned in \( x \). If no IP solution was found \text{lower} \) contains the same bounds as supplied by the user in \text{bl}. The first \( n \) elements contain the lower bounds on the variables, and the next \( m \) elements contain the lower bounds for the general linear constraints (if any).

**upper** – double *

Input: \( n+m \) values of memory will be automatically allocated by \text{nag_ipmip}_\text{bb} \) and this is the recommended method of use of \text{options.upper}. However a user may supply memory from the calling program.

Output: the upper bounds imposed at the point returned in \( x \). If no IP solution was found \text{upper} \) contains the same bounds as supplied by the user in \text{bu}. The first \( n \) elements contain the upper bounds on the variables, and the next \( m \) elements contain the upper bounds for the general linear constraints (if any).

**state** – Integer *

Input: \( n+m \) values of memory will be automatically allocated by \text{nag_ipmip}_\text{bb} \) and this is the recommended method of use of \text{options.state}. However a user may supply memory from the calling program.

Output: the status of the constraints in the working set at the point returned in \( x \). The significance of each possible value of \text{state}[j] \) is as follows:

<table>
<thead>
<tr>
<th>state[j]</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>−2</td>
<td>The constraint violates its lower bound by more than the feasibility tolerance.</td>
</tr>
<tr>
<td>−1</td>
<td>The constraint violates its upper bound by more than the feasibility tolerance.</td>
</tr>
</tbody>
</table>
0 The constraint is satisfied to within the feasibility tolerance, but is not in the working set.
1 This inequality constraint is included in the working set at its lower bound.
2 This inequality constraint is included in the working set at its upper bound.
3 This constraint is included in the working set as an equality. This value of state can occur only when $bl[j] = bu[j]$.
4 This corresponds to optimality being declared with $x[j]$ being temporarily fixed at its current value. This value of state can only occur if the optimal solution is not unique.

\[ \text{Input: } n+m \text{ values of memory will be automatically allocated by nag_ip_bb and this is the recommended method of use of options.lambda. However a user may supply memory from the calling program.} \]

\[ \text{Output: the values of the Lagrange multipliers for each constraint with respect to the current working set at the point returned in } x. \] The first $n$ elements contain the multipliers (reduced costs) for the bound constraints on the variables, and the next $m$ elements contain the multipliers (shadow costs) for the general linear constraints (if any). If $\text{state}[j] = 0$, $\text{lambda}[j]$ is zero. If $x$ is optimal, $\text{lambda}[j]$ should be non-negative if $\text{state}[j] = 1$, non-positive if $\text{state}[j] = 2$ and zero if $\text{state}[j] = 4$.

8.3. Description of Printed Output

The level of printed output can be controlled by the user with the structure members options.list and options.print_level (see Section 8.2). If list = TRUE then the parameter values to nag_ip_bb are listed, whereas the printout of results is governed by the value of print_level. The default of print_level = Nag_Soln.Iter provides intermediate and final results.

If print_level = Nag_Iter, Nag_Soln.Iter or Nag_Soln.Root.Iter, the following line of summary output is produced at the end of every node. It gives the outcome of forcing an integer variable with a non-integer value to take a value within its specified lower and upper bounds.

- **Node No** is the current node number of the BB tree being investigated.
- **Parent Node** is the parent node number of the current node.
- **Obj Value** is the final objective function value. If a node does not have a feasible solution then Infeasible is printed instead of the objective function value. If a node whose optimum solution exceeds the best integer solution so far is encountered (i.e., it does not pay to explore the sub-problem any further), then its objective function value is printed together with a CO (Cut Off).
- **Varbl Chosen** is the index of the integer variable chosen for branching.
- **Value Before** is the non-integer value of the integer variable chosen.
- **Lower Bound** is the lower bound value that the integer variable is allowed to take.
- **Upper Bound** is the upper bound value that the integer variable is allowed to take.
- **Value After** is the value of the integer variable after the current optimization.
- **Depth** is the depth of the BB tree at the current node.

If print_level = Nag_Soln.Root or Nag_Soln.Root.Iter, the root node solution is output before the BB search is commenced. If print_level = Nag_Soln, Nag_Soln.Iter, Nag_Soln.Root or Nag_Soln.Root.Iter the final IP solution or, if none was found, the root node solution is output.

The following describes the printout for each variable and constraint for both root node and final IP solution printout.
Varbl gives the name of variable \( j \), for \( j = 1, 2, \ldots, n \). If an \texttt{options} structure is supplied to nag_ip_bb, and the \texttt{crnames} member is assigned to an array of variable and constraint names (see Section 8.2 for details), the name supplied in \texttt{crnames}[j - 1] is assigned to the \( j \)th variable. Otherwise, a default name is assigned to the variable.

State gives the state of the variable (\texttt{FR} if neither bound is in the working set, \texttt{EQ} if a fixed variable, \texttt{LL} if on its lower bound, \texttt{UL} if on its upper bound, \texttt{TF} if temporarily fixed at its current value). If \texttt{Value} lies outside the upper or lower bounds by more than the feasibility tolerance, \texttt{State} will be ++ or -- respectively.

Value is the value of the variable at the final iteration.

Lower Bound is the lower bound \( l_j \) specified for the variable. (\texttt{None} indicates that \( l_j \leq -\texttt{inf_bound} \), where \texttt{inf_bound} is the optional parameter.) For root node printout, \( l_j = \texttt{bl}[j - 1] \); for IP solution printout, \( l_j \) is the lower bound imposed at the node which provided the IP solution.

Upper Bound is the upper bound \( u_j \) specified for the variable. (\texttt{None} indicates that \( u_j \geq \texttt{inf_bound} \).) For root node printout, \( u_j = \texttt{bu}[j - 1] \); for IP solution printout, \( u_j \) is the upper bound imposed at the node which provided the IP solution.

Lagr Mult is the value of the Lagrange multiplier for the associated bound constraint. This will be zero if \texttt{State} is \texttt{FR} or \texttt{TF}. If \( x \) is optimal, the multiplier should be non-negative if \texttt{State} is \texttt{LL}, and non-positive if \texttt{State} is \texttt{UL}.

Residual is the difference between the variable \texttt{Value} and the nearer of its bounds \( l_j \) and \( u_j \).

The meaning of the printout for general constraints is the same as that given above for variables, with ‘variable’ replaced by ‘constraint’, \( n \) replaced by \( m \), \texttt{crnames}[j - 1] replaced by \texttt{crnames}[n + j - 1], \( l_j \) and \( u_j \) replaced by \( l_{n+i} \) and \( u_{n+i} \) respectively, and with the following change in the heading:

\textbf{Constr} gives the name of constraint \( i \), \( i = 1, 2, \ldots, m \). If an \texttt{options} structure is supplied to nag_ip_bb, and the \texttt{crnames} member is assigned to an array of variable and constraint names (see Section 8.2 for details), the name supplied in \texttt{crnames}[n+i-1] is assigned to the constraint. Otherwise, a default name is assigned to the constraint.

Numerical values are output with a fixed number of digits; they are not guaranteed to be accurate to this precision.

If \texttt{options.print_level = Nag_NoPrint} then printout will be suppressed; the user can print the final solution when nag_ip_bb returns to the calling program.

8.3.1. Output of results via a user defined printing function

The user may also specify their own print function for output of iteration results and the final solution by use of the \texttt{options.print_fun} function pointer, which has prototype

\begin{verbatim}
void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm);
\end{verbatim}

This section may be skipped by a user who only wishes to use the default printing facilities.

When a user-defined function is assigned to \texttt{options.print_fun} this will be called in preference to the internal print function of nag_ip_bb. Calls to the user defined function are again controlled by means of the \texttt{options.print_level} member. Information is provided through \texttt{st} and \texttt{comm}, the two structure arguments to \texttt{print_fun}.

If \texttt{comm->node_prt = TRUE} then the results from the most recently solved node are provided through \texttt{st}. Note that \texttt{print_fun} will be called with \texttt{comm->node_prt = TRUE} only if \texttt{print_level = Nag_Iter, Nag_Soln_Iter} or \texttt{Nag_Soln_Root_Iter}. The following members of \texttt{st} are set:

\texttt{node_num} – Integer

the current node number of the BB tree being investigated.

\texttt{parent_node} – Integer

the parent node number of the current node.
node_status – Nag_NodeStatus
the status of the current node. The possible values of node_status and their meanings are as follows:

- Nag_NS_NotBranched: the node has been solved but the branch cannot yet be eliminated from the search.
- Nag_NS_Integer: an integer solution was found at this node. There is no need to search this branch further.
- Nag_NS_Bounded: the objective value exceeds the upper bound on the optimal IP solution. There is no need to search this branch further.
- Nag_NS_Infeasible: the problem was infeasible at this node. There is no need to search this branch further.
- Nag_NS_Terminated: the iteration limit was exceeded at this node. The search has to be terminated prematurely for this branch.

objf – double
if st->node_status = Nag_NS_NotBranched, Nag_NS_Integer or Nag_NS_Bounded, then objf holds the objective value.

branch_index – Integer
the index in x of the variable chosen for branching.

x_lo – double
the lower bound on the branching variable.

x_up – double
the upper bound on the branching variable.

x_before – double
the non-integer value of the branching variable before the node was solved.

x_after – double
the value of the branching variable after the node was solved.

depth – Integer
the depth of the BB tree at the current node.

If comm->rootnode_sol_prt = TRUE then the solution of the root node is provided through st. Note that print_fun will be called with comm->rootnode_sol_prt = TRUE only if print_level = Nag_Soln_Root or Nag_Soln_Root_Iter. The following members of st are set:

endstate – Nag_EndState
the state of termination of the sub-problem solver at the root node. Some of these states result in immediate termination of the algorithm. If this is the case, then no valid solution is available. The other states allow the algorithm to proceed with the BB tree search. Possible values of endstate and their correspondence, if any, to the exit value of fail.code from nag_ip_bb are:

Value of endstate Value of fail.code
--------- ---------------------------------
Nag_Optimal (BB search may proceed)
Nag_Deadpoint (BB search may proceed)
Nag_Weakmin (BB search may proceed)
Nag_Unbounded NE_MIP_ROOT_UNBOUNDED
Nag_Infeasible NE_MIP_ROOT_INFEAS
Nag_Too_Many_Iter NE_MIP_ROOT_MAX_ITER
Nag_Hess_Too_Big NE_MIP_ROOT_HESS_TOO_BIG

n – Integer
the number of variables.
The following members of the NagPack structures are available. The state of termination of nag will be called with nag\_comm\_sol\_prt = TRUE only if nag\_print\_level = Nag_SOLn, Nag_SOLn\_Root, Nag_SOLn\_Iter, or Nag_SOLn\_Root\_Iter. If no IP solution was found then the root node solution is available. The endstate member of st should be examined to determine the status of the solution. The following members of st are set:

### endstate

The state of termination of nag\_ip\_bb. Possible values of endstate and their correspondence to the exit value of fail\_code are shown below.

<table>

</tbody>
</table>

### n

The number of variables.

### m

The number of linear constraints.

### nnodes

The number of nodes examined during the BB tree search.

### objf

The value of the objective function.

---

m – Integer

the number of linear constraints.

objf – double

the value of the objective function.

x – double

the components x[j − 1] of the solution x, for j = 1, 2,..., st\_n.

ax – double

if st\_m > 0, ax[j − 1] contains the components of the linear constraint vector, for j = 1, 2,..., st\_m.

state – Integer *

contains the status of the st\_n variables and st\_m general linear constraints. See Section 8.2 for a description of the possible status values.

lambda – double *

contains the st\_n + st\_m values of the Lagrange multipliers.

bl – double *

contains the st\_n + st\_m lower bounds on the variables.

bu – double *

contains the st\_n + st\_m upper bounds on the variables.

If comm\_sol\_prt = TRUE then the final IP solution is provided through st. Note that print\_fun will be called with comm\_sol\_prt = TRUE only if print\_level = Nag_SOLn, Nag_SOLn\_Root, Nag_SOLn\_Iter, or Nag_SOLn\_Root\_Iter. If no IP solution was found then the root node solution is available. The endstate member of st should be examined to determine the status of the solution. The following members of st are set:

### endstate

The state of termination of nag\_ip\_bb
x – double
  the components $x[j-1]$ of the solution $x$, for $j = 1, 2, \ldots, st->n$.

ax – double
  if $st->m > 0$, $ax[j-1]$ contains the components of the linear constraint vector, for
  $j = 1, 2, \ldots, st->m$.

state – Integer *
  contains the status of the $st->n$ variables and $st->m$ general linear constraints. See Section
  8.2 for a description of the possible status values.

lambda – double *
  contains the $st->n + st->m$ values of the Lagrange multipliers.

bl – double *
  contains the $st->n + st->m$ lower bounds on the variables.

bu – double *
  contains the $st->n + st->m$ upper bounds on the variables.

The relevant members of the structure comm are:

rootnode_solprt – Boolean
  will be TRUE when the print function is called with the solution of the root node.

nodeprt – Boolean
  will be TRUE when the print function is called with the result of the most recently solved
  node.

solprt – Boolean
  will be TRUE when the print function is called with the final solution.

user – double *

iuser – Integer *

p – Pointer
  pointers for communication of user information. If used they must be allocated memory by
  the user either before entry to nag_ip_bb or during a call to qphess or print_fun. The type
  Pointer will be void * with a C compiler that defines void * and char * otherwise.

9. Error Indications and Warnings

NE_USER_STOP
  User requested termination, user flag value = ⟨value⟩.

This exit occurs if the user sets comm->flag to a negative value in qphess. If fail is supplied
the value of fail.errnum will be the same as the user’s setting of comm->flag.

NE_INT_ARG_LT
  On entry, $n$ must not be less than 1: $n = ⟨value⟩$.
  On entry, $m$ must not be less than 0: $m = ⟨value⟩$.

NE_2_INT_ARG_LT
  On entry, $tda = ⟨value⟩$ while $n = ⟨value⟩$. These parameters must satisfy $tda \geq n$.
  On entry, $tdh = ⟨value⟩$ while $n = ⟨value⟩$. These parameters must satisfy $tdh \geq n$.
  On entry, $tdh = ⟨value⟩$ while options.hrows = ⟨value⟩. These parameters must satisfy $tdh
  \geq hrows$.

NE_OPT_NOT_INIT
  Options structure not initialized.

NE_BAD_PARAM
  On entry parameter options.prob had an illegal value.
  On entry parameter options.print_level had an illegal value.
  On entry parameter options.nodsel had an illegal value.
  On entry parameter options.varsel had an illegal value.
  On entry parameter options.branch_dir had an illegal value.
h - Operations Research

NE_INVALID_RANGE_1
Value ⟨value⟩ given to options.max_iter is not valid. Correct range is max_iter ≥ 0.
Value ⟨value⟩ given to options.max_nodes is not valid. Correct range is max_nodes = ALL_NODES or max_nodes ≥ 1.
Value ⟨value⟩ given to options.max_depth is not valid. Correct range is max_depth ≥ 2.
Value ⟨value⟩ given to options.hrows is not valid. Correct range is n ≥ hrows ≥ 0.
Value ⟨value⟩ given to options.max_df is not valid. Correct range is n ≥ max_df ≥ 1.

NE_INVALID_REAL_RANGE_F
Value ⟨value⟩ given to options.int_tol is not valid. Correct range is 0.0 < int_tol < 1.0.
Value ⟨value⟩ given to options.rank_tol is not valid. Correct range is 0.0 ≤ rank_tol < 1.0.

NE_INVALID_REAL_RANGE_FF
Value ⟨value⟩ given to options.sohn_tol is not valid. Correct range is sohn_tol ≥ 0.0.
Value ⟨value⟩ given to options.feas_tol is not valid. Correct range is feas_tol > 0.0.
Value ⟨value⟩ given to options.inf_bound is not valid. Correct range is inf_bound > 0.0.

NE_CVEC_NULL
options.prob = ⟨value⟩ but argument cvec = NULL.

NE_H_NULL
options.prob = ⟨value⟩, qphess is NULL but argument h is also NULL. If the default function for qphess is to be used for this problem then an array must be supplied in parameter h.

NE_PRIORITY_NULL
options.varsel = Nag_Use_Priority but options.priority is NULL.

NE_NAME_TOO_LONG
The character string pointed to by options.cnames[⟨value⟩] is too long. It should be no longer than 8 characters.

NE_BOUND
The lower bound for variable ⟨value⟩ (array element bl[⟨value⟩]) is greater than the upper bound.

NE_BOUND_ICON
The lower bound for linear constraint ⟨value⟩ (array element bl[⟨value⟩]) is greater than the upper bound.

NE_ALLOC_FAIL
Memory allocation failed.

NE_MIP_ROOT_UNBOUNDED
The root node of the BB tree appears to be unbounded.
See Section 10 for advice.

NE_MIP_ROOT_INFEAS
The root node of the BB tree is infeasible.
A feasible point could not be found for the original LP or QP problem, i.e., it was not possible to satisfy all the constraints to within the feasibility tolerance (determined by optional parameter feas_tol). If the data for the constraints are accurate only to the absolute precision σ, the user should ensure that the value of the feasibility tolerance is greater than σ. For example, if all elements of A are of order unity and are accurate only to three decimal places, the feasibility tolerance should be at least 10^{-3} (see Section 10).

NE_MIP_ROOT_MAX_ITER
The maximum number of iterations, ⟨value⟩, was performed before normal termination occurred for the root node of the BB tree.
The maximum number of iterations (determined by optional parameter max_iter) was reached before normal termination occurred for the original LP or QP problem (see Section 10).

NW_MIP_NO_INT_SOL
No feasible IP solution was found, i.e., it was not possible to satisfy all the integer variables to within optional parameter int_tol.
It may be appropriate to increase int_tol and rerun nag_ip_bb.
NW_MIP_MAX_ITER_INT_SOL
The IP solution found may not be the optimum. The search had to be terminated in at least one branch of the BB tree because the iteration limit was reached.

It was not possible to solve at least one node of the BB tree, which means that the tree search could not be completed. An IP solution was found but a better one may be present in the unsearched portion of the tree. See Section 10 for more information.

NW_MIP_MAX_ITER_NO_INT_SOL
No IP solution was found but the search had to be terminated in at least one branch of the BB tree because the iteration limit was reached.

It was not possible to solve at least one node of the BB tree, which means that the tree search could not be completed. No IP solution was found but one may be present in the unsearched portion of the tree. See Section 10 for more information.

NW_MIP_MAX_NODES_INT_SOL
The IP solution found is the best for the number of nodes (as determined by optional parameter max_nodes) investigated in the BB tree.

Increase max_nodes and rerun nag_ip_bb. The IP objective obtained should be assigned to options.int_obj_bound to aid the BB tree search in the repeated run.

NW_MIP_MAX_NODES_NO_INT_SOL
No integer solution was found for the number of nodes (as determined by options.max_nodes) investigated in the BB tree.

Increase max_nodes and rerun nag_ip_bb.

NW_MIP_MAX_DEPTH_INT_SOL
An IP solution was found but the search has been terminated because the maximum allowed tree depth (as determined by optional parameter max_depth) has been reached.

Increase max_depth and rerun nag_ip_bb. The IP objective obtained should be assigned to options.int_obj_bound to aid the BB tree search in the repeated run.

NW_MIP_MAX_DEPTH_NO_INT_SOL
The maximum allowed tree depth (as determined by optional parameter max_depth) has been reached before any integer solution has been found.

Increase max_depth and rerun nag_ip_bb.

NE_MIP_ROOT_HESS_TOO_BIG
Reduced Hessian exceeds assigned dimension at root node.

options.max_df = ⟨value⟩.

This error can only occur with MIQP problems. Whilst attempting to solve the root node, the QP algorithm needed to expand the reduced Hessian when it was already at its maximum dimension, as specified by the optional parameter max_df.

The value of the parameter max_df is too small. Rerun nag_ip_bb with a larger value.

NE_MIP_HESS_TOO_BIG_INT_SOL
Reduced Hessian exceeds assigned dimension during BB tree search.

options.max_df = ⟨value⟩. An IP solution was found.

This error can only occur with MIQP problems. Whilst attempting to solve a node during the BB tree search, the QP algorithm needed to expand the reduced Hessian when it was already at its maximum dimension, as specified by the optional parameter max_df. No further nodes were examined. An IP solution was found but it may not be optimal.

The value of the parameter max_df is too small. Rerun nag_ip_bb with a larger value. The IP objective obtained should be assigned to options.int_obj_bound to aid the BB tree search in the repeated run.
NE_MIP_HESS_TOO_BIG_NO_INT_SOL
Reduced Hessian exceeds assigned dimension during BB tree search.
\texttt{options.max_df = \langle value\rangle}. No IP solution was found.

This error can only occur with MIQP problems. Whilst attempting to solve a node during the
BB tree search, the QP algorithm needed to expand the reduced Hessian when it was already
at its maximum dimension, as specified by the optional parameter \texttt{max_df}. No further nodes
were examined. No IP solution was found amongst the nodes examined.

The value of the parameter \texttt{max_df} is too small. Rerun \texttt{nag_ip_bb} with a larger value.

NW_OVERFLOW_WARN
Serious ill-conditioning in the working set after adding constraint \( \langle \text{value} \rangle \). Overflow may
occur in subsequent iterations.

If overflow occurs preceded by this warning then serious ill-conditioning has probably occurred
in the working set when adding a constraint during the solution of a node in the BB tree. It
may be possible to avoid the difficulty by increasing the magnitude of the optional parameter
\texttt{feas_tol} and rerunning the program. If the problem recurs even after this change, see
Section 10.

NE_NOT_APPEND_FILE
Cannot open file \langle string \rangle for appending.

NE_WRITE_ERROR
Error occurred when writing to file \langle string \rangle.

NE_NOT_CLOSE_FILE
Cannot close file \langle string \rangle.

NE_INTERNAL_ERROR
An internal error has occurred in this function. Check the function call and any array sizes.
If the call is correct then please consult NAG for assistance.

10. Further Comments

The root node may not have an optimum solution, i.e., \texttt{nag_ip_bb} terminates with \texttt{fail.code = NE_MIP_ROOT_UNBOUNDED}, \texttt{NE_MIP_ROOT_INFEAS}, \texttt{NE_MIP_ROOT_MAX_ITER},
\texttt{NE_MIP_ROOT_HESS_TOO_BIG} or overflow may occur. In this case, the user is recommended to
relax the integer restrictions of the problem and try to find the optimum LP or QP solution by
using \texttt{nag_opt_lp (e04mfc)} (for LP) or \texttt{nag_opt_qp (e04nfc)} (for QP) instead.

In the BB method, it is possible for a node to terminate without finding a solution. For example, this
may occur due to the number of iterations exceeding the maximum allowed. Therefore the BB tree
search for that particular branch cannot be continued and if an IP solution is found, the final solution
reported is not necessarily the optimum IP solution (\texttt{fail.code = NW_MIP_MAX_ITER_INT_SOL}).
Similarly, if no IP solution is found, it is not necessarily the case that no IP solution exists
(\texttt{fail.code = NW_MIP_MAX_ITER_NO_INT_SOL}).

10.1 Accuracy
The function implements a numerically stable active set strategy and returns solutions that are as
accurate as the condition of the problem warrants on the machine.

13. Example 2

One of the applications of integer programming is to the so-called diet problem. Given the nutritional content of a selection of foods, the cost of each food, the amount available of each food and the consumer’s minimum daily energy requirements, the problem is to find the cheapest combination. This gives rise to the following problem:

\[
\text{minimize } c^T x \text{ subject to } Ax \geq b, \ 0 \leq x \leq u,
\]

where

\[
c = (3 \ 24 \ 13 \ 9 \ 20 \ 19)^T, \ x = (x_1, x_2, x_3, x_4, x_5, x_6)^T \text{ is integer,}
\]

\[
A = \begin{pmatrix}
110 & 205 & 160 & 160 & 420 & 260 \\
4 & 32 & 13 & 8 & 4 & 14 \\
2 & 12 & 54 & 285 & 22 & 80
\end{pmatrix}, \ b = \begin{pmatrix}
2000 \\
55 \\
800
\end{pmatrix} \text{ and }
\]

\[
u = (4 \ 3 \ 2 \ 8 \ 2 \ 2)^T.
\]

The rows of \(A\) correspond to energy, protein and calcium and the columns of \(A\) correspond to oatmeal, chicken, eggs, milk, pie and bacon respectively.

The following program solves the above problem to obtain the optimal integer solution and then examines the effect of decreasing the energy required to 1970 units. The example involves a number of calls to \textit{nag\_ip\_bb} illustrating the use of some of the optional parameters.

The data is read and the options structure initialised. All options are left at their default values except: the \texttt{crnames} member is assigned to the local \texttt{char *} array, \texttt{crnames}, the elements of which point to strings containing the variable and constraint names; and \texttt{print\_level} is set to \texttt{Nag\_Soln}.

\texttt{nag\_ip\_bb} is called to obtain the optimal IP solution of the problem, and then the lower bound on the minimum energy constraint (i.e., the first general constraint) is reduced. Since the problem is now less constrained than the original IP problem, the objective function value returned in \texttt{objf} from the original problem provides an upper bound for the objective of the optimal IP solution of the modified problem. Optional parameter \texttt{int\_obj\_bound} is initialised to this value with a small number added to ensure that it is a strict upper bound on the optimal objective of the modified problem. Also, the optional parameter \texttt{nodsel} is set to \texttt{Nag\_Deep\_Search} to modify the way \texttt{nag\_ip\_bb} selects nodes during the tree search. The results from this show that the value assigned to \texttt{int\_obj\_bound} allow a number of nodes to be cut off (indicated by \texttt{CO} in the printout) before the first IP solution is found.

Next, the effect of supplying branching directions is illustrated. The optional parameter \texttt{branch\_dir} is set to \texttt{Nag\_Branch\_InitX} to instruct \texttt{nag\_ip\_bb} to branch according to the values of the integer variables provided in the initial \texttt{x} parameter. In this case \texttt{x} contains the optimal IP solution from the last call of \texttt{nag\_ip\_bb}. The results show that these values allow \texttt{nag\_ip\_bb} to find and confirm the optimal IP solution quickly.

The final two calls to \texttt{nag\_ip\_bb} show its use in solving an MIQP problem. First, \texttt{nag\_ip\_bb} is called with the \texttt{intvar} parameter set to an array \texttt{intvar2} which specifies all variables to be non-integer.
This solves the root LP problem of the adjusted diet problem (as solved in the previous three calls to nag_ip_bb). Let \( x^* \) be the solution to this LP problem. Then, retaining the same constraints, the linear objective is replaced by the quadratic objective

\[
\sum_{i=1}^{n} (x_i - x_i^*)^2 - \sum_{i=1}^{n} (x_i^*)^2 = x^T x - 2(x^*)^T x
\]

which measures, to within a constant, the sum of squares deviation of \( x \) from \( x^* \). That is, the problem is to find the IP solution which most closely approximates (in the least-squares sense) the LP solution. Before solving this problem, the memory assigned to the pointers in the options structure is freed by nag_ip_free (h02zc) and the structure is reinitialised by nag_ip_free (h02zc). Then optional parameter prob is set to Nag_MIQP2 and crnames is assigned as before; otherwise, default options are used. The quadratic term of the objective is supplied via the function qphess which does not require explicit storage for the matrix \( H \). nag_ip_bb is called to solve the MIQP problem, and finally nag_ip_free (h02zc) is called to free the memory in options.
